|                 |                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prompt <i>p</i> | change the <code>fsdb</code> prompt to <i>p</i> . <i>p</i> must be surrounded by (")s.                                                                                                                                                                                          |
| pwd             | display the current working directory.                                                                                                                                                                                                                                          |
| quit            | quit <code>fsdb</code> .                                                                                                                                                                                                                                                        |
| sb              | the value of <i>dot</i> is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, 'sb' at the beginning of a line will set the value of <i>dot</i> to the superblock and display it in superblock format. |
| shadow          | if the current inode is a shadow inode, then the value of <i>dot</i> is set to the beginning of the shadow inode data.                                                                                                                                                          |
| !               | escape to shell                                                                                                                                                                                                                                                                 |

### Inode Commands

In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current `inode` (they still require the ':'). They may be used to more easily display or change the particular fields. The value of *dot* is only used by the ':db' and ':ib' commands. Upon completion of the command, the value of *dot* is changed to point to that particular field. For example,

```
> :ln+=1
```

would increment the link count of the current `inode` and set the value of *dot* to the address of the link count field.

at        access time.

bs        block size.

ct        creation time.

db        use the current value of *dot* as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the `block` or `fragment` command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the inode and convert it to a block address. 20 longs are then displayed in hexadecimal. See `FormattedOutput`.

gid        group id.

ib        use the current value of *dot* as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the `file` command and start at block 12 to get to the actual blocks.

ln link count.

mt modification time.

md mode.

maj major device number.

min minor device number.

nm although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the *directory* command), this command will allow you to change or display the directory name. For example,

```
> 7:dir:nm="foo"
```

will get the 7th directory entry of the current inode and change its name to foo. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.

si shadow inode.

sz file size.

uid user id.

**Formatted Output**

There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

?

```

c display as cylinder groups
i display as inodes
d display as directories
s display as superblocks
S display as shadow inode data

```

/

```

b display as bytes
c display as characters
o O display as octal shorts or longs
d D display as decimal shorts or longs
x X display as hexadecimal shorts or longs The format specifier

```

immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, type is appropriately updated upon completion.

**EXAMPLES**

- > 2000+400%(20+20)=D  
will display 2010 in decimal (use of fsdb as a calculator for complex arithmetic).
- > 386:ino?i  
display i-number 386 in an inode format. This now becomes the current inode.
- > :ln=4  
changes the link count for the current inode to 4.
- > :ln+=1  
increments the link count by 1.
- > :ct=X  
display the creation time as a hexadecimal long.
- > :mt=t  
display the modification time in time format.
- > 0:file/c  
displays, in ASCII, block zero of the file associated with the current inode.
- > 2:ino,\*?d  
displays the first blocks worth of directory entries for the root inode of this file system. It will stop prematurely if the EOF is reached.
- > 5:dir:inode; 0:file,\*/c  
changes the current inode to that associated with the 5th directory entry (numbered from zero) of the current inode. The first logical block of the file is then displayed in ASCII.
- > :sb  
displays the superblock of this file system.
- > 1:cg?c  
displays cylinder group information and summary for cylinder group 1.
- > 2:inode; 7:dir=3  
changes the i-number for the seventh directory slot in the root directory to 3.
- > 2:db:block,\*?d  
displays the third block of the current inode as directory entries.
- > 7:dir:nm="name"  
changes the name field in the directory slot to *name*.
- > 3c3:fragment,20:fill=0x20  
get fragment 3c3 and fill 20 type elements with 0x20.
- > 2050=0xfffff  
set the contents of address 2050 to 0xffffffff. 0xffffffff may be truncated depending on the current type.

```
> 1c92434="this is some text"
 will place the ASCII for the string at 1c92434.
> 2:ino:si:ino;0:shadow,*?S
 displays all of the shadow inode data in the shadow inode associated with the root
 inode of this file system.
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `clri(1M)`, `fsck_ufs(1M)`, `dir_ufs(4)`, `fs_ufs(4)`, `attributes(5)`

**WARNINGS** Since `fsdb` reads the disk raw, extreme caution is advised in determining its availability of `fsdb` on the system. Suggested permissions are 600 and owned by bin.

**NOTES** The old command line syntax for clearing i-nodes using the ufs-specific `'-z i-number'` option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolescence of this option to the command. The equivalent functionality is available using the more flexible `clri(1M)` command.

fsirand(1M)

**NAME** fsirand – install random inode generation numbers

**SYNOPSIS** **fsirand** [-p] *special*

**DESCRIPTION** fsirand installs random inode generation numbers on all the inodes on device *special*, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.

fsirand must be used only on an unmounted file system that has been checked with fsck(1M) The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.

**OPTIONS** -p Print out the generation numbers for all the inodes, but do not change the generation numbers.

**USAGE** See largefile(5) for the description of the behavior of fsirand when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** fsck(1M), attributes(5), largefile(5)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>DESCRIPTION</b> | <p>The <code>fssnap</code> command creates a stable, read-only snapshot of a file system when given either an active mount point or a special device containing a mounted file system, as in the first form of the synopsis. A snapshot is a temporary image of a file system intended for backup operations.</p> <p>A path to the virtual device that contains this snapshot is printed to standard output when a snapshot is created.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Deletes the snapshot associated with the given file system.</li> <li><code>-F FSType</code> Specifies the file system type to be used. The <code>FSType</code> should either be specified here or be determined by matching the block special device with an entry in the <code>/etc/vfstab</code> table, or by consulting <code>/etc/default/fs</code>.</li> <li><code>-i</code> Displays the state of any given <code>FSType</code> snapshot. If a mount-point or device is not given, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default. The format and meaning of this information is file-system dependent. See the <code>FSType</code>-specific <code>fssnap</code> man page for details.</li> <li><code>-o special_options</code> See the <code>FSType</code>-specific man page for <code>fssnap</code>.</li> <li><code>-V</code> Echoes the complete command line, but does not execute the command.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><code>mount-point</code> The directory where the file system resides.</li> <li><code>special</code> The physical device for the system, such as <code>/dev/dsk/c0t0d0s7</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>EXAMPLES</b>    | See <code>FSType</code> -specific man pages for examples.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b> | <p>The <code>fssnap</code> command queries, creates, or deletes a temporary snapshot of a UFS file system. A snapshot is a point-in-time image of a file system that provides a stable and unchanging device interface for backups.</p> <p>When creating a file system snapshot, you must specify the file system to be captured and the backing-store file.</p> <p>The backing-store file is one in which the snapshot subsystem saves old file system data before it is overwritten. The destination path must have enough free space to hold the backing-store file, whose size varies with the amount of activity on the file system. This location must be different from the file system that is being captured in a snapshot. The backing-store file can reside on any type of file system, including another UFS file system or an NFS-mounted file system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-d</code><br/>Deletes the snapshot associated with the given file system.</p> <p><code>-i</code><br/>Displays the state of one or all UFS snapshots. If a mount-point or device is not specified, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default.</p> <p>Use the <code>-o</code> options with the <code>-i</code> option to specify what snapshot information is displayed. Since this feature is provided primarily for use in scripts and on the command line, no labels are displayed for the data. Sizes are all in bytes, and the output is not internationalized or localized. The information is displayed on one line per option. Unrecognized options display a single <code>?</code> on the line. One line per option guarantees that there are the same number of lines as options specified and there is a one-to-one correspondence between an output line and an option.</p> <p>The following <code>-o</code> options display specific information for a given snapshot. See the <b>EXAMPLES</b> section for examples of how to use these options.</p> <p><code>snapnumber</code><br/>Display the snapshot number.</p> <p><code>blockdevname</code><br/>Display the block device path.</p> |

rawdevname

Display the raw device path.

mountpoint

Display the mount point of the master file system.

state

Display the state of the snapshot device.

backing-store

Display the location of the backing-store file.

backing-store-len

Display the size of the backing-store file.

maxsize

Display the max size of the backing-store file.

createtime

Display the time that the snapshot was created.

chunksize

Display the copy-on-write granularity.

-o *specific-options*

Without `-d` or `-i`, the default action is to create a snapshot. Specify the following options when creating a snapshot. All of these options are discretionary, except for the backing-store file (`bs`), which is required.

`backing-store=path`

Uses *path* as the backing-store file. *path* must not reside on the file system that is being captured in a snapshot.

*path* must exist, and must be either a directory, a regular file, or a raw device. If *path* is a directory, then a temporary file is created and held open. That device is then used as-is. The option can be abbreviated as `bf=path` or `bs=path`.

`unlink`

Unlinks the backing-store file after the snapshot is created. This option specifies that the backing-store file does not need to be removed manually when the snapshot is deleted. This might make administration more difficult since the file is not visible in the file system. If this option is not specified, the backing-store files should be removed manually after the snapshot is deleted.

`chunksize=n [k,m,g]`

Uses *n* for the chunk size. Chunk size is the granularity of the data that is sent to the backing store.

Specify `chunksize` in the following units: `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. By default, chunk size is four times the block size of the file system (typically 32k).

`maxsize=n[k,m,g]`

Does not allow the size of the backing-store file to exceed *n*, where *n* is the unit specified. The snapshot is deleted automatically when the backing-store file exceeds `maxsize`.

Specify `maxsize` in the following units: `k` for kilobytes, `m` for megabytes, or `g` for gigabytes.

`raw`

Displays to standard output the name of the raw device instead of the block device when a snapshot is created. The block device is printed by default (when `raw` is not specified). This option makes it easier to embed `fssnap` commands in the command line for commands that require the raw device instead. Both devices are always created. This option affects only the output.

**OPERANDS** The following operands are supported:

*mount-point* The directory where the file system resides.

*special* The physical device for the file system, such as `/dev/dsk/c0t0d0s7`.

**EXAMPLES** **EXAMPLE 1** Creating a Snapshot of a File System

The following example creates a snapshot of a file system. The block special device created for the snapshot is `/dev/fssnap/0`.

```
fssnap -F ufs -o backing-store=/var/tmp /export/home
/dev/fssnap/0
```

**EXAMPLE 2** Backing Up a File System Snapshot Without Having To Unmount the File System

The following example backs up a file system snapshot without having to unmount the file system. Since `ufsdump` requires the path to a raw device, the `raw` option is used. The `/export/home` file system snapshot is removed in the second command.

```
ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
-o raw,bs=/dev/rdisk/c0t3d0s6 /export/home`
<output from ufsdump>
fssnap -F ufs -d /export/home
```

**EXAMPLE 3** Backing Up a File System

When backing up a file system, do not let the backing-store file exceed 400 Mbytes. The second command removes the `/export/home` file system snapshot.

```
ufsdump 0uf /dev/rmt/0 `fssnap -F ufs
-o maxsize=400m,backing-store=/export/snap,raw
/export/home`
fssnap -F ufs -d /export/home
```

**EXAMPLE 3** Backing Up a File System (Continued)**EXAMPLE 4** Performing an Incremental Dump of a Snapshot

The following example uses `ufsdump` to back up a snapshot of `/dev/rdisk/c0t3d0s2`. Note the use of the `N` option to `ufsdump`, which writes the name of the device being dumped, rather than the name of the snapshot device, to `/etc/dumpdates` file. See `ufsdump(1M)` for details on the `N` flag.

```
ufsdump lfNu /dev/rmt/0 /dev/rdisk/c0t3d0s2 `fssnap -F ufs
-o raw,bs=/export/scratch,unlink /dev/rdisk/c0t3d0s2`
```

**EXAMPLE 5** Finding Out What Snapshots Currently Exist

The following command displays the currently existing snapshots.

```
fssnap -i
0 /src
1 /export/home
<output continues>
```

**EXAMPLE 6** Mounting a File System Snapshot

The following example creates a file system snapshot. After you create a file system snapshot, mount it on `/tmp/mount` for temporary read-only access.

```
fssnap -F ufs -o backing-store=/nfs/server/scratch /export/home
/dev/fssnap/1
mkdir /tmp/mount
mount -F ufs -o ro /dev/fssnap/1 /tmp/mount
```

**EXAMPLE 7** Creating a File System Snapshot and Unlinking the Backing-store File

The following example creates a file system snapshot and unlinks the backing-store file. After creating a file system snapshot and unlinking the backing-store file, check the state of the snapshot.

```
fssnap -o bs=/scratch,unlink /src
/dev/fssnap/0
fssnap -i /src
Snapshot number : 0
Block Device : /dev/fssnap/0
Raw Device : /dev/rfssnap/0
Mount point : /src
Device state : active
Backing store path : /scratch/snapshot2 <UNLINKED>
Backing store size : 192 KB
Maximum backing store size : Unlimited
Snapshot create time : Sat May 06 10:55:11 2000
Copy-on-write granularity : 32 KB
```

**EXAMPLE 7** Creating a File System Snapshot and Unlinking the Backing-store File  
(Continued)

**EXAMPLE 8** Displaying the Size and Location of the Backing-store File and the Creation Time for the Snapshot

The following example displays the size of the backing-store file in bytes, the location of the backing store, and the creation time for the snapshot of the /test file system.

```
fssnap -i -o backing-store-len,backing-store,createtime /test
196608
/snapshot2
Sat May 6 10:55:11 2000
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

The script-readable output mode is a stable interface that can be added to, but will not change. All other interfaces are subject to change.

**NOTES** The `fssnap` device files should be treated like a regular disk block or character device.

The association between a file system and the snapshot is lost when the snapshot is deleted or the system reboots. Snapshot persistence across reboots is not currently supported.

To avoid unnecessary performance impacts, perform the snapshot and system backup when the system is least active.

## fstyp(1M)

| <b>NAME</b>        | <code>fstyp</code> – determine file system type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>fstyp</code> [-v] <i>special</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><code>fstyp</code> allows the user to determine the file system type of unmounted file systems using heuristic programs.</p> <p>An <code>fstyp</code> module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied <i>special</i> file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, “ufs”) and exits with a return code of 0; if none of the modules succeed, the error message <code>unknown_fstyp</code> (no matches) is returned and the exit status is 1. If more than one module succeeds, the error message <code>unknown_fstyp</code> (multiple matches) is returned and the exit status is 2.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <code>-v</code> Produce verbose output. This is usually information about the file systems superblock and varies across different <i>FSTypes</i> . See <code>fs_ufs(4)</code> , <code>mkfs_ufs(1M)</code> , and <code>tunefs(1M)</code> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>fstyp</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
|                    | <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| <b>NAME</b>                  | fuser – identify processes using a file or file structure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>              | <code>/usr/sbin/fuser [- [c   f]ku] files [ [- [c   f]ku] files] ...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b>           | <p>fuser displays the process IDs of the processes that are using the <i>files</i> specified as arguments.</p> <p>Each process ID is followed by a letter code. These letter codes are interpreted as follows: if the process is using the file as</p> <ul style="list-style-type: none"> <li>c        Indicates that the process is using the file as its current directory.</li> <li>m        Indicates that the process is using a file mapped with <code>mmap(2)</code>. See <code>mmap(2)</code> for details.</li> <li>o        Indicates that the process is using the file as an open file.</li> <li>r        Indicates that the process is using the file as its root directory.</li> <li>t        Indicates that the process is using the file as its text file.</li> <li>y        Indicates that the process is using the file as its controlling terminal.</li> </ul> <p>For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.</p> <p>If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.</p> <p>The process IDs are printed as a single line on the standard output, separated by spaces and terminated with a single new line. All other output is written on standard error.</p> <p>Any user can run fuser, but only the superuser can terminate another user's process.</p> |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c        Reports on files that are mount points for file systems, and any files within that mounted file system.</li> <li>-f        Print a report for the named file, not for files within a mounted file system.</li> <li>-k        Sends the <code>SIGKILL</code> signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see <code>kill(2)</code>).</li> <li>-u        Displays the user login name in parentheses following the process ID.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of fuser: <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## fuser(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

**NOTES** Because `fuser` works with a snapshot of the system image, it may miss processes that begin using a file while `fuser` is running. Also, processes reported as using a file may have stopped using it while `fuser` was running. These factors should discourage the use of the `-k` option.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>NAME</b>        | fwtmp, wtmpfix – manipulate connect accounting records                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <code>/usr/lib/acct/fwtmp [-ic]</code><br><code>/usr/lib/acct/wtmpfix [file...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in <code>/var/adm/wtmpx</code> to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.</p> <p>wtmpfix examines the standard input or named files in utmpx format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (-) can be used in place of <i>file</i> to indicate the standard input. If time/date corrections are not performed, acctcon(1M) will fault when it encounters certain date-change records.</p> <p>Each time the date is set, a pair of date change records are written to <code>/var/adm/wtmpx</code>. The first record is the old date denoted by the string "old time" placed in the <code>line</code> field and the flag <code>OLD_TIME</code> placed in the <code>type</code> field of the utmpx structure. The second record specifies the new date and is denoted by the string <code>new time</code> placed in the <code>line</code> field and the flag <code>NEW_TIME</code> placed in the <code>type</code> field. wtmpfix uses these records to synchronize all time stamps in the file.</p> <p>In addition to correcting time/date stamps, wtmpfix will check the validity of the <code>name</code> field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to <code>INVALID</code> and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that acctcon will fail when processing connect accounting records.</p> |
| <b>OPTIONS</b>     | <code>-ic</code> Denotes that input is in ASCII form, and output is to be written in binary form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>        | <code>gencc</code> – create a front-end to the <code>cc</code> command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <code>gencc</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>gencc</code> command is an interactive command designed to aid in the creation of a front-end to the <code>cc</code> command. Since hard-coded pathnames have been eliminated from the C Compilation System (CCS), it is possible to move pieces of the CCS to new locations without recompilation. The new locations of moved pieces can be specified through the <code>-Y</code> option to the <code>cc</code> command. However, it is inconvenient to supply the proper <code>-Y</code> options with every invocation of the <code>cc</code> command. Further, if a system administrator moves pieces of the CCS, such movement should be invisible to users.</p> <p>The front-end to the <code>cc</code> command that <code>gencc</code> generates is a one-line shell script that calls the <code>cc</code> command with the proper <code>-Y</code> options specified. The front-end to the <code>cc</code> command will also pass all user-supplied options to the <code>cc</code> command.</p> <p><code>gencc</code> prompts for the location of each tool and directory that can be respecified by a <code>-Y</code> option to the <code>cc</code> command. If no location is specified, it assumes that that piece of the CCS has not been relocated. After all the locations have been prompted for, <code>gencc</code> will create the front-end to the <code>cc</code> command.</p> <p><code>gencc</code> creates the front-end to the <code>cc</code> command in the current working directory and gives the file the same name as the <code>cc</code> command. Thus, <code>gencc</code> can not be run in the same directory containing the actual <code>cc</code> command. Further, if a system administrator has redistributed the CCS, the actual <code>cc</code> command should be placed in a location that is not typically in a user's path (for example, <code>/usr/lib</code>). Such placement will prevent users from accidentally invoking the <code>cc</code> command without using the front-end.</p> |
| <b>FILES</b>       | <code>./cc</code> front-end to <code>cc</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>DESCRIPTION</b>      | <p>getdev generates a list of devices that match certain criteria. The criteria includes a list of attributes (given in expressions) and a list of devices. If no criteria are given, all devices are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list unless the -a option is used. Then, only those devices which match all of the criteria in a list will be included.</p> <p>Devices which are defined on the command line and which match the criteria are included in the generated list. However, if the -e option is used, the list becomes a set of devices to be <i>excluded</i> from the list. See <b>OPTIONS</b> and <b>OPERANDS</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |                                                                                                |                         |                                                                                                   |                    |                                                                        |                     |                                                                               |
| <b>OPTIONS</b>          | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</li> <li>-e        Specifies that the list of devices which follows on the command line should be <i>excluded</i> from the list generated by this command. Without the -e the named devices are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |                                                                                                |                         |                                                                                                   |                    |                                                                        |                     |                                                                               |

getdev(1M)

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table could not be opened for reading.

**FILES** /etc/device.tab

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `devattr(1M)`, `getdgrp(1M)`, `putdev(1M)`, `putdgrp(1M)`, `attributes(5)`

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |

| <b>DESCRIPTION</b>       | getdgrp generates a list of device groups that contain devices matching the given criteria. The criteria is given in the form of expressions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>OPTIONS</b>           | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.</li> <li>-e        Specifies that the list of device groups on the command line should be <i>excluded</i> from the list generated by this command. Without the -e option the named device groups are <i>included</i> in the generated list. The flag has no effect if no devices are defined.</li> <li>-1        Specifies that all device groups (subject to the -e option and the <i>dgroup</i> list) should be listed even if they contain no valid device members. This option has no affect if <i>criteria</i> is specified on the command line.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <b>OPERANDS</b>          | <p>The following operands are supported:</p> <p><i>criteria</i>        Defines criteria that a device must match before a device group to which it belongs can be included in the generated list. Specify <i>criteria</i> as an expression or a list of expressions which a device must meet for its group to be included in the list generated by getdgrp. If no criteria are given, all device groups are included in the list.</p> <p>Devices must satisfy at least one of the criteria in the list. However, the -a option can be used to define that a "logical and" operation should be performed. Then, only those groups containing devices which match all of the criteria in a list will be included.</p> <p>There are four possible expressions types which the criteria specified in the <i>criteria</i> argument may follow:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><i>attribute=value</i></td> <td>Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i>.</td> </tr> <tr> <td style="padding-right: 20px;"><i>attribute !=value</i></td> <td>Selects all device groups with a member whose attribute <i>attribute</i> is defined and does not equal <i>value</i>.</td> </tr> <tr> <td style="padding-right: 20px;"><i>attribute : *</i></td> <td>Selects all device groups with a member which has the attribute <i>attribute</i> defined.</td> </tr> </table> | <i>attribute=value</i> | Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i> . | <i>attribute !=value</i> | Selects all device groups with a member whose attribute <i>attribute</i> is defined and does not equal <i>value</i> . | <i>attribute : *</i> | Selects all device groups with a member which has the attribute <i>attribute</i> defined. |
| <i>attribute=value</i>   | Selects all device groups with a member whose attribute <i>attribute</i> is defined and is equal to <i>value</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <i>attribute !=value</i> | Selects all device groups with a member whose attribute <i>attribute</i> is defined and does not equal <i>value</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |
| <i>attribute : *</i>     | Selects all device groups with a member which has the attribute <i>attribute</i> defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                        |                                                                                                                    |                          |                                                                                                                       |                      |                                                                                           |

## getdgrp(1M)

*attribute!* : \*                      Selects all device groups with a member which does not have the attribute *attribute* defined.

See `putdev(1M)` for a complete listing and description of available attributes.

### *dgroup*

Defines a set of device groups which should be included in or excluded from the generated list. Device groups that are defined and which contain devices matching the criteria are included.

If the `-e` option is used, this list defines a set of device groups to be excluded. When the `-e` option is used and *criteria* is also defined, the generated list will include device groups containing devices which match the criteria and are not in the command line list.

**EXIT STATUS**      The following exit values are returned:

- 0            Successful completion of the task.
- 1            Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2            Device table or device group table could not be opened for reading.

**FILES**            `/etc/device.tab`  
                    `/etc/dgroup.tab`

**ATTRIBUTES**     See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>               | getent – get entries from administrative database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                           |                                               |                    |                      |                   |                   |                        |                                |                          |                                         |                      |                                      |                       |                               |                    |                                                        |                      |                              |
| <b>SYNOPSIS</b>           | <b>getent</b> <i>database</i> [ <i>key...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                           |                                               |                    |                      |                   |                   |                        |                                |                          |                                         |                      |                                      |                       |                               |                    |                                                        |                      |                              |
| <b>DESCRIPTION</b>        | <p>getent gets a list of entries from the administrative database specified by <i>database</i>. The information generally comes from one or more of the sources that are specified for the <i>database</i> in <i>/etc/nsswitch.conf</i>.</p> <p><i>database</i> is the name of the database to be examined. This can be <i>passwd</i>, <i>group</i>, <i>hosts</i>, <i>ipnodes</i>, <i>services</i>, <i>protocols</i>, <i>ethers</i>, <i>networks</i>, or <i>netmasks</i>. For each of these databases, getent uses the appropriate library routines described in <i>getpwnam(3C)</i>, <i>getgrnam(3C)</i>, <i>gethostbyaddr(3NSL)</i>, <i>gethostbyname(3NSL)</i>, <i>getipnodebyaddr(3SOCKET)</i>, <i>getipnodebyname(3SOCKET)</i>, <i>getservbyname(3SOCKET)</i>, <i>getprotobyname(3SOCKET)</i>, <i>ethers(3SOCKET)</i>, and <i>getnetbyname(3SOCKET)</i>, respectively.</p> <p>Each <i>key</i> must be in a format appropriate for searching on the respective database. For example, it can be a <i>username</i> or <i>numeric-uid</i> for <i>passwd</i>; <i>hostname</i> or <i>IP address</i> for <i>hosts</i>; or <i>service</i>, <i>service/protocol</i>, <i>port</i>, or <i>port/proto</i> for <i>services</i>.</p> <p>getent prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: <i>passwd(4)</i>, <i>group(4)</i>, <i>hosts(4)</i>, <i>ipnodes(4)</i>, <i>services(4)</i>, <i>protocols(4)</i>, <i>ethers(3SOCKET)</i>, <i>networks(4)</i>, or <i>netmasks(4)</i>. If no key is given, all entries returned by the corresponding enumeration library routine, for example, <i>getpwent()</i> or <i>gethostent()</i>, are printed. Enumeration is not supported on <i>ipnodes</i>.</p> |                           |                                               |                    |                      |                   |                   |                        |                                |                          |                                         |                      |                                      |                       |                               |                    |                                                        |                      |                              |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/gettable host</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>gettable is a simple program used to obtain the DoD Internet host table from a “hostname” server. The specified <i>host</i> is queried for the table. The table is placed in the file <code>hosts.txt</code>.</p> <p>gettable operates by opening a TCP connection to the port indicated in the service specification for “hostname”. A request is then made for all names and the resultant information is placed in the output file.</p> <p>gettable is best used in conjunction with the <code>htable(1M)</code> program which converts the DoD Internet host table format to that used by the network library lookup routines.</p> |                |                 |              |          |

| <b>SYNOPSIS</b>    | <code>/usr/lib/saf/ttymon [-h] [-t <i>timeout</i>] <i>line</i> [<i>speed</i> [<i>type</i> [<i>linedisc</i>]]]</code><br><code>/usr/lib/saf/ttymon -c <i>file</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>getty sets terminal type, modes, speed, and line discipline. <code>getty</code> is a symbolic link to <code>/usr/lib/saf/ttymon</code>. It is included for compatibility with previous releases for the few applications that still call <code>getty</code> directly.</p> <p><code>getty</code> can only be executed by the super-user, (a process with the user ID <code>root</code>). Initially <code>getty</code> prints the login prompt, waits for the user's login name, and then invokes the <code>login</code> command. <code>getty</code> attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.</p> <p>Without optional arguments, <code>getty</code> specifies the following: The <i>speed</i> of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. <code>getty</code> types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause <code>getty</code> to attempt the next <i>speed</i> in the series. The series that <code>getty</code> tries is determined by what it finds in <code>/etc/ttydefs</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-h</code> If the <code>-h</code> flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to the default or a specified speed.</li><li><code>-t <i>timeout</i></code> Specifies that <code>getty</code> should exit if the open on the line succeeds and no one types anything in <i>timeout</i> seconds.</li><li><code>-c <i>file</i></code> The <code>-c</code> option is no longer supported. Instead use <code>/usr/sbin/sttydefs -l</code> to list the contents of the <code>/etc/ttydefs</code> file and perform a validity check on the file.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>line</i> The name of a TTY line in <code>/dev</code> to which <code>getty</code> is to attach itself. <code>getty</code> uses this string as the name of a file in the <code>/dev</code> directory to open for reading and writing.</li><li><i>speed</i> The <i>speed</i> argument is a label to a speed and TTY definition in the file <code>/etc/ttydefs</code>. This definition tells <code>getty</code> at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default <i>speed</i> is 300 baud.</li><li><i>type</i> and <i>linedisc</i> These options are obsolete and will be ignored.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>NAME</b>        | getvol – verifies device accessibility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/getvol -n [-l <i>label</i>] <i>device</i><br/>/usr/bin/getvol [-f   -F] [-ow] [-l <i>label</i>   -x <i>label</i>] <i>device</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | getvol verifies that the specified device is accessible and that a volume of the appropriate medium has been inserted. The command is interactive and displays instructional prompts, describes errors, and shows required label information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-n Runs the command in non-interactive mode. The volume is assumed to be inserted upon command invocation.</li><li>-l <i>label</i> Specifies that the label <i>label</i> must exist on the inserted volume (can be overridden by the -o option).</li><li>-f Formats the volume after insertion, using the format command defined for this device in the device table.</li><li>-F Formats the volume after insertion and places a file system on the device. Also uses the format command defined for this device in the device table.</li><li>-o Allows the administrator to override a label check.</li><li>-w Allows administrator to write a new label on the device. User is prompted to supply the label text. This option is ineffective if the -n option is enabled.</li><li>-x <i>label</i> Specifies that the label <i>label</i> must exist on the device. This option should be used in place of the -l option when the label can only be verified by visual means. Use of the option causes a message to be displayed asking the administrator to visually verify that the label is indeed <i>label</i>.</li></ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>device</i> Specifies the device to be verified for accessibility.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0 Successful completion.</li><li>1 Command syntax was incorrect, invalid option was used, or an internal error occurred.</li><li>3 Device table could not be opened for reading.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/groupadd [-g <i>gid</i> [-o]] <i>group</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | The groupadd command creates a new group definition on the system by adding the appropriate entry to the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-g <i>gid</i></code> Assigns the group id <i>gid</i> for the new group. This group id must be a non-negative decimal integer below <code>MAXUID</code> as defined in <code>/usr/include/sys/param.h</code>. The group ID defaults to the next available (unique) number above the highest number currently assigned. For example, if groups 100, 105, and 200 are assigned as groups, the next default group number will be 201. (Group IDs from 0–99 are reserved by SunOS for future applications.)</p> <p><code>-o</code> Allows the <i>gid</i> to be duplicated (non-unique).</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>group</i> A string consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if the string exceeds <code>MAXGLEN</code>, which is usually set at eight characters. The <i>group</i> field must contain at least one character; it accepts lower case or numeric characters or a combination of both, and must not contain a colon (:) or NEWLINE.</p>                                                                                                                                                         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>2 Invalid command syntax. A usage message for the groupadd command is displayed.</p> <p>3 An invalid argument was provided to an option.</p> <p>4 The <i>gid</i> is not unique (when <code>-o</code> option is not used).</p> <p>9 The <i>group</i> is not unique.</p> <p>10 The <code>/etc/group</code> file cannot be updated.</p>                                                                                                                                                                                                                     |
| <b>FILES</b>       | <code>/etc/group</code><br><code>/usr/include/userdefs.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

groupadd(1M)

**SEE ALSO** users(1B), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

**NOTES** groupadd only adds a group definition to the local system. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, groupadd cannot change information supplied by the network name service. However, groupadd will verify the uniqueness of group name and group ID against the external name service.

groupdel(1M)

**NAME** groupdel – delete a group definition from the system

**SYNOPSIS** `/usr/sbin/groupdel group`

**DESCRIPTION** The `groupdel` utility deletes a group definition from the system. It deletes the appropriate entry from the `/etc/group` file.

**OPERANDS** `group` An existing group name to be deleted.

**EXIT STATUS** The following exit values are returned:

- 0 Success.
- 2 Invalid command syntax. A usage message for the `groupdel` command is displayed.
- 6 `group` does not exist.
- 10 Cannot update the `/etc/group` file.

**FILES** `/etc/group` system file containing group definitions

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `users(1B)`, `groupadd(1M)`, `groupmod(1M)`, `logins(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `attributes(5)`

**NOTES** The `groupdel` utility only deletes a group definition that is in the local `/etc/group` file. If a network nameservice such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, `groupdel` cannot change information supplied by the network nameservice.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>NAME</b>        | groupmod – modify a group definition on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/groupmod [-g <i>gid</i> [-o]] [-n <i>name</i>] <i>group</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | The <code>groupmod</code> command modifies the definition of the specified group by modifying the appropriate entry in the <code>/etc/group</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-<i>gid</i> Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than <code>MAXUID</code>, as defined in <code>&lt;param.h&gt;</code>. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)</li> <li>-o Allow the <i>gid</i> to be duplicated (non-unique).</li> <li>-<i>name</i> Specify the new name for the group. The <i>name</i> argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The <i>name</i> argument must contain at least one character and must not include a colon (<code>:</code>) or NEWLINE (<code>\n</code>).</li> </ul> |
| <b>OPERANDS</b>    | The following operands are supported: <ul style="list-style-type: none"> <li><i>group</i> An existing group name to be modified.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EXIT STATUS</b> | The <code>groupmod</code> utility exits with one of the following values: <ul style="list-style-type: none"> <li>0 Success.</li> <li>2 Invalid command syntax. A usage message for the <code>groupmod</code> command is displayed.</li> <li>3 An invalid argument was provided to an option.</li> <li>4 <i>gid</i> is not unique (when the <code>-o</code> option is not used).</li> <li>6 <i>group</i> does not exist.</li> <li>9 <i>name</i> already exists as a group name.</li> <li>10 Cannot update the <code>/etc/group</code> file.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## groupmod(1M)

**SEE ALSO** users(1B), groupadd(1M), groupdel(1M), logins(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

**NOTES** The groupmod utility only modifies group definitions in the `/etc/group` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/group` file with additional entries, groupmod cannot change information supplied by the network name service. The groupmod utility will, however, verify the uniqueness of group name and group ID against the external name service.

| <b>NAME</b>                    | gsscred – add, remove and list gsscred table entries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                    |                                |                                        |                 |                         |                             |                                                                |                             |                                      |                            |                                                       |                 |                                  |                            |                                                                                               |
| <b>SYNOPSIS</b>                | <pre>gsscred [-n <i>user</i> [-o <i>oid</i>] [-u <i>uid</i>]] [-c <i>comment</i>] -m <i>mech</i> -a gsscred [-n <i>user</i> [-o <i>oid</i>]] [-u <i>uid</i>] [-m <i>mech</i>] -r gsscred [-n <i>user</i> [-o <i>oid</i>]] [-u <i>uid</i>] [-m <i>mech</i>] -l</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                    |                                |                                        |                 |                         |                             |                                                                |                             |                                      |                            |                                                       |                 |                                  |                            |                                                                                               |
| <b>DESCRIPTION</b>             | <p>The <code>gsscred</code> utility is used to create and maintain a mapping between a security principal name and a local UNIX <code>uid</code>. The format of the user name is assumed to be <code>GSS_C_NT_USER_NAME</code>. You can use the <code>-o</code> option to specify the object identifier of the <code>name</code> type. The OID must be specified in dot-separated notation, for example: <code>1.2.3.45464.3.1</code>.</p> <p>The <code>gsscred</code> table is used on server machines to lookup the <code>uid</code> of incoming clients connected using <code>RPCSEC_GSS</code>.</p> <p>When adding users, if no <code>user</code> name is specified, an entry is created in the table for each user from the <code>passwd</code> table. If no <code>comment</code> is specified, the <code>gsscred</code> utility inserts a comment that specifies the user name as an ASCII string and the GSS-API security mechanism that applies to it. The security mechanism will be in string representation as defined in the <code>/etc/gss/mech</code> file.</p> <p>The parameters are interpreted the same way by the <code>gsscred</code> utility to delete users as they are to create users. At least one of the following options must be specified: <code>-n</code>, <code>-u</code>, or <code>-m</code>. If no security mechanism is specified, then all entries will be deleted for the user identified by either the <code>uid</code> or <code>user</code> name. If only the security mechanism is specified, then all <code>user</code> entries for that security mechanism will be deleted.</p> <p>Again, the parameters are interpreted the same way by the <code>gsscred</code> utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the <code>user</code> name or <code>uid</code> is specified, then all entries for that <code>user</code> are returned. If a security mechanism is specified, then all <code>user</code> entries for that security mechanism are returned.</p> |                 |                    |                                |                                        |                 |                         |                             |                                                                |                             |                                      |                            |                                                       |                 |                                  |                            |                                                                                               |

## gsscred(1M)

### EXAMPLES

#### EXAMPLE 1 Creating a gsscred Table for the Kerberos v5 Security Mechanism

The following shows how to create a `gsscred` table for the kerberos v5 security mechanism. `gsscred` obtains *user* names and *uid*'s from the `passwd` table to populate the table.

```
example% gsscred -m kerberos_v5 -a
```

#### EXAMPLE 2 Adding an Entry for root/host1 for the Kerberos v5 Security Mechanism

The following shows how to add an entry for `root/host1` with a specified *uid* of 0 for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a
```

#### EXAMPLE 3 Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -l
```

#### EXAMPLE 4 Listing All Mappings for All Security Mechanism for a Specified User

The following lists all mappings for all security mechanisms for the user `bsimpson`.

```
example% gsscred -n bsimpson -l
```

### EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

| <b>NAME</b>        | gssd – generates and validates GSS-API tokens for kernel RPC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <code>/usr/lib/gss/gssd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <code>gssd</code> is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, <code>gssd</code> maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. <code>gssd</code> is invoked by the Internet daemon <code>inetd(1m)</code> the first time that the kernel RPC requests GSS-API services. |
| <b>EXIT STATUS</b> | The following exit values are returned:<br>0                   Successful completion.<br>>0                   An error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                            |

## halt(1M)

| <b>NAME</b>        | halt, poweroff – stop the processor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>/usr/sbin/halt [-dlnqy]</code><br><code>/usr/sbin/poweroff [-dlnqy]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>halt</code> and <code>poweroff</code> utilities write any pending information to the disks and then stop the processor. The <code>poweroff</code> utility will have the machine remove power, if possible.</p> <p>The <code>halt</code> and <code>poweroff</code> utilities normally log the system shutdown to the system log daemon, <code>syslogd(1M)</code>, and place a shutdown record in the login accounting file <code>/var/adm/wtmpx</code>. These actions are inhibited if the <code>-n</code> or <code>-q</code> options are present.</p>                                           |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-d</code> Force a system crash dump before rebooting. See <code>dumpadm(1M)</code> for information on configuring system crash dumps.</li><li><code>-l</code> Suppress sending a message to the system log daemon, <code>syslogd(1M)</code>, about who executed <code>halt</code>.</li><li><code>-n</code> Prevent the <code>sync(1M)</code> before stopping.</li><li><code>-q</code> Quick halt. No graceful shutdown is attempted.</li><li><code>-y</code> Halt the system, even from a dialup terminal.</li></ul> |                |                 |              |         |
| <b>FILES</b>       | <code>/var/adm/wtmpx</code> history of user access and administration information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/bin/hostconfig -p protocol [-d] [-h] [-n] [-v] [-i interface] [-f hostname]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>hostconfig</code> program uses a network protocol to acquire a machine’s <i>host parameters</i> and set these parameters on the system.</p> <p>The program selects which protocol to use based on the argument to the required <code>-p</code> flag. Different protocols may set different host parameters. Currently, only one protocol (<code>bootparams</code>) is defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Enable debug output.</li> <li><code>-f hostname</code> Run the protocol as if this machine were named <code>hostname</code>.</li> <li><code>-h</code> Echo the received <code>hostname</code> to <code>stdout</code>, rather than setting <code>hostname</code> using the system name directly.</li> <li><code>-i interface</code> Use only the named network interface to run the protocol.</li> <li><code>-n</code> Run the network protocol, but do not set the acquired parameters into the system.</li> <li><code>-p protocol</code> Run <code>hostconfig</code> using <code>protocol</code>. Currently, only one protocol (<code>bootparams</code>) is available. This option is required.</li> </ul> <p>Specifying the <code>-p bootparams</code> option uses the <code>whoami</code> call of the RPC <code>bootparams</code> protocol. This sets the system’s <code>hostname</code>, <code>domainname</code>, and default IP router parameters.</p> <ul style="list-style-type: none"> <li><code>-v</code> Enable verbose output.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Configuring host parameters with verbose output</p> <p>The following command configures a machine’s host parameters using the <code>whoami</code> call of the RPC <code>bootparams</code> protocol with a verbose output.</p> <pre>example# hostconfig -p bootparams -v</pre> <p><b>EXAMPLE 2</b> Displaying host parameters</p> <p>The following command displays the parameters that would be set using the <code>whoami</code> call of the RPC <code>bootparams</code> protocol.</p> <pre>example# hostconfig -p bootparams -n -v</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## hostconfig(1M)

**EXAMPLE 3** Configuring host parameters less the system name

The following command configures a machine's host parameters, less the system name, using the `whoami` call of the RPC `bootparams` protocol.

```
example# hostconfig='hostconfig -p bootparams -h'
```

| <b>SYNOPSIS</b>    | <code>/usr/sbin/htable filename</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: <code>hosts</code>, <code>networks</code>, and <code>gateways</code>. The <code>hosts</code> file is used by the <code>gethostbyname(3NSL)</code> routines in mapping host names to addresses. The <code>networks</code> file is used by the <code>getnetbyname(3SOCKET)</code> routines in mapping network names to numbers. The <code>gateways</code> file is used by the routing daemon to identify “passive” Internet gateways.</p> <p>If any of the files <code>localhosts</code>, <code>localnetworks</code>, or <code>localgateways</code> are present in the current directory, the file’s contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.</p> <p>htable is best used in conjunction with the <code>gettable(1M)</code> program which retrieves the DoD Internet host table from a host.</p> |                |                 |              |          |
| <b>FILES</b>       | <p><code>localhosts</code></p> <p><code>localnetworks</code></p> <p><code>localgateways</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |          |

| <b>DESCRIPTION</b> | <p>If no <i>user</i> operand is provided, the <i>id</i> utility writes the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both are written. If multiple groups are supported by the underlying system, <i>/usr/xpg4/bin/id</i> also writes the supplementary group affiliations of the invoking process.</p> <p>If a <i>user</i> operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user are written. In this case, effective IDs are assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, <i>/usr/xpg4/bin/id</i> writes them in the same manner as the supplementary groups described in the preceding paragraph.</p>                                                                                                                                                                                                                                                                   |
| <b>Formats</b>     | <p>The following formats are used when the <code>LC_MESSAGES</code> locale category specifies the "C" locale. In other locales, the strings <code>uid</code>, <code>gid</code>, <code>eid</code>, <code>egid</code>, and <code>groups</code> may be replaced with more appropriate strings corresponding to the locale.</p> <pre>"uid=%u(%s) gid=%u(%s)\n" &lt;real user ID&gt;, &lt;user-name&gt;, &lt;real group ID&gt;, &lt;group-name&gt;</pre> <p>If the effective and real user IDs do not match, the following are inserted immediately before the <code>\n</code> character in the previous format:</p> <pre>" eid=%u(%s) "</pre> <p>with the following arguments added at the end of the argument list:</p> <pre>&lt;effective user ID&gt;, &lt;effective user-name&gt;</pre> <p>If the effective and real group IDs do not match, the following is inserted directly before the <code>\n</code> character in the format string (and after any addition resulting from the effective and real user IDs not matching):</p> <pre>" egid=%u(%s) "</pre> <p>with the following arguments added at the end of the argument list:</p> |

*<effectivegroup-ID>, <effectivegroupname>*

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first is added directly before the NEWLINE character in the format string:

```
" groups=%u (%s) "
```

with the following arguments added at the end of the argument list:

*<supplementary group ID>, <supplementary group name>*

and the necessary number of the following added after that for any remaining supplementary group IDs:

```
", %u (%s) "
```

and the necessary number of the following arguments added at the end of the argument list:

*<supplementary group ID>, <supplementary group name>*

If any of the user ID, group ID, effective user ID, effective group ID or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding (%s) and name argument is omitted from the corresponding format string.

When any of the options are specified, the output format is as described under OPTIONS.

**OPTIONS** The following option is supported by both `/usr/bin/id` and `/usr/xpg4/bin/id`. For `/usr/xpg4/bin/id`, `-p` is invalid if specified with any of the `-G`, `-g`, or `-u` options.

`-p` Reports additionally the current project membership of the invoking process. The project is reported using the format:

```
"projid=%u (%s) "
```

which is inserted prior to the `\n` character of the default format described in the `Formats` section. The arguments

*<project ID>, <project name>*

are appended to the end of the argument list. If the project ID cannot be mapped by the system into a printable project name, the corresponding (%s) and name argument is omitted from the corresponding format string.

**/usr/bin/id** The following option is supported for `/usr/bin/id` only:

id(1M)

- a Reports user name, user ID and all the groups to which the user belongs.

**/usr/xpg4/bin/id**

The following options are supported for `/usr/xpg4/bin/id` only:

- G Output all different group IDs (effective, real and supplementary) only, using the format "`%u\n`". If there is more than one distinct group affiliation, output each such affiliation, using the format " `%u`", before the NEWLINE character is output.
- g Output only the effective group ID, using the format "`%u\n`".
- n Output the name in the format "`%s`" instead of the numeric ID using the format "`%u`".
- r Output the real ID instead of the effective ID.
- u Output only the effective user ID, using the format "`%u\n`".

**OPERANDS**

The following operand is supported:

*user* The user (login) name for which information is to be written.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `id`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/id**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
|                | SUNWcar         |

**/usr/xpg4/bin/id**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

**SEE ALSO**

`fold(1)`, `logname(1)`, `who(1)`, `getgid(2)`, `getgroups(2)`, `getprojid(2)`, `getuid(2)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

**NOTES**

Output produced by the `-G` option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>        | ifconfig – configure network interface parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <pre> <b>/sbin/ifconfig</b> interface [address_family] [address [/prefix_length] [dest_address]] [addif address [/prefix_length]] [removeif address [/prefix_length]] [arp   -arp] [auth_algs authentication algorithm] [encr_algs encryption algorithm] [encr_auth_algs authentication algorithm] [auto-revarp] [broadcast address] [deprecated   -deprecated] [destination dest_address] [ [failover]   [-failover]] [group [ [name]   ""]] [index {if_index}] [metric n] [modlist] [modinsert mod_name@pos] [modremove mod_name@pos] [mtu n] [netmask mask] [plumb] [unplumb] [private   -private] [nud   -nud] [set [address] [/netmask]] [ [standby]   [-standby]] [subnet subnet_address] [tdst tunnel_dest_address] [tsrc tunnel_src_address] [trailers   -trailers] [up] [down] [xmit   -xmit]  <b>/usr/sbin/ifconfig</b> interface [address_family] [address [/prefix_length] [dest_address]] [addif address [/prefix_length]] [removeif address [/prefix_length]] [arp   -arp] [auth_algs authentication algorithm] [encr_algs encryption algorithm] [encr_auth_algs authentication algorithm] [auto-revarp] [broadcast address] [deprecated   -deprecated] [destination dest_address] [ [failover]   [-failover]] [group [ [name]   ""]] [index {if_index}] [metric n] [modlist] [modinsert mod_name@pos] [modremove mod_name@pos] [mtu n] [netmask mask] [plumb] [unplumb] [private   -private] [nud   -nud] [set [address] [/netmask]] [ [standby]   [-standby]] [subnet subnet_address] [tdst tunnel_dest_address] [tsrc tunnel_src_address] [trailers   -trailers] [up] [down] [xmit   -xmit]  <b>/sbin/ifconfig</b> interface {auto-dhcp   dhcp} [primary] [wait seconds] drop   extend   inform   ping   release   start   status  <b>/usr/sbin/ifconfig</b> interface {auto-dhcp   dhcp} [primary] [wait seconds] drop   extend   inform   ping   release   start   status </pre> |
| <b>DESCRIPTION</b> | <p>The command <code>ifconfig</code> is used to assign an address to a network interface and to configure network interface parameters. The <code>ifconfig</code> command must be used at boot time to define the network address of each interface present on a machine; it may also be used at a later time to redefine an interface's address or other operating parameters. If no option is specified, <code>ifconfig</code> displays the current configuration for a network interface. If an address family is specified, <code>ifconfig</code> reports only the details specific to that address family. Only the superuser may modify the configuration of a network interface. Options appearing within braces (<code>{ }</code>) indicate that one of the options must be specified.</p> <p>The two versions of <code>ifconfig</code>, <code>/sbin/ifconfig</code> and <code>/usr/sbin/ifconfig</code>, behave differently with respect to name services. The order in which names are looked</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## ifconfig(1M)

up by `/sbin/ifconfig` when the system is booting is fixed and cannot be changed. In contrast, changing `/etc/nsswitch.conf` may affect the behavior of `/usr/sbin/ifconfig`. The system administrator may configure the source and lookup order in the tables by means of the name service switch. See `nsswitch.conf(4)` for more information.

### DHCP Configuration

The third and fourth forms of this command are used to control the Dynamic Host Configuration Protocol (“DHCP”) configuring of the interface. DHCP is only available on interfaces for which the address family is `inet`. In this mode, `ifconfig` is used to control operation of `dhcpcd(1M)`, the DHCP client daemon. Once an interface is placed under DHCP control by using the `start` operand, `ifconfig` should not, in normal operation, be used to modify the address or characteristics of the interface. If the address of an interface under DHCP is changed, `dhcpcd` will remove the interface from its control.

### OPTIONS

The following options are supported:

`addif address`

Create the next unused logical interface on the specified physical interface.

`arp`

Enable the use of the Address Resolution Protocol (“ARP”) in mapping between network level addresses and link level addresses (default). This is currently implemented for mapping between IPv4 addresses and 10Mb/s Ethernet addresses.

`-arp`

Disable the use of the ARP.

`auth_algs authentication algorithm`

For a tunnel, enable IPsec AH with the authentication algorithm specified. The algorithm can be either a number or an algorithm name, including *any* to express no preference in algorithm. All IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify an `auth_alg` of *none*.

`auto-dhcp`

Use DHCP to automatically acquire an address for this interface. This option has a completely equivalent alias called `dhcp`.

`primary`

Defines the interface as the `primary`. The interface is defined as the preferred one for the delivery of client-wide configuration data. Only one interface can be the primary at any given time. If another interface is subsequently selected as the primary, it replaces the previous one. Nominating an interface as the primary one will not have much significance once the client work station has booted, as many applications will already have started and been configured with data read from the previous primary interface.

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wait <i>seconds</i></code>      | The <code>ifconfig</code> command will wait until the operation either completes or for the interval specified, whichever is the sooner. If no wait interval is given, and the operation is one that cannot complete immediately, <code>ifconfig</code> will wait 30 seconds for the requested operation to complete. The symbolic value <code>forever</code> may be used as well, with obvious meaning.                                                                 |
| <code>drop</code>                     | Remove the specified interface from DHCP control. Additionally, set the IP address to zero and mark the interface as “down”.                                                                                                                                                                                                                                                                                                                                             |
| <code>extend</code>                   | Attempt to extend the lease on the interface’s IPv4 address. This is not required, as the agent will automatically extend the lease well before it expires.                                                                                                                                                                                                                                                                                                              |
| <code>inform</code>                   | Obtain network configuration parameters from DHCP without obtaining a lease on an IP address. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.                                                                                                                                                                                                                                                                           |
| <code>ping</code>                     | Check whether the interface given is under DHCP control, which means that the interface is managed by the DHCP agent and is working properly. An exit status of 0 means success. This subcommand has no meaning when the named interface represents more than one interface.                                                                                                                                                                                             |
| <code>release</code>                  | Relinquish the IPv4 address on the interface, and mark the interface as “down.”                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>start</code>                    | Start DHCP on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>status</code>                   | Display the DHCP configuration status of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>auto-revarp</code>              | Use the Reverse Address Resolution Protocol (“RARP”) to automatically acquire an address for this interface.                                                                                                                                                                                                                                                                                                                                                             |
| <code>broadcast <i>address</i></code> | For IPv4 only. Specify the address to use to represent broadcasts to the network. The default broadcast address is the address with a host part of all 1’s. A “+” (plus sign) given for the broadcast value causes the broadcast address to be reset to a default appropriate for the (possibly new) address and netmask. The arguments of <code>ifconfig</code> are interpreted left to right. Therefore<br><br>example% <code>ifconfig -a netmask + broadcast +</code> |
| <code>and</code>                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## ifconfig(1M)

```
example% ifconfig -a broadcast + netmask +
```

may result in different values being assigned for the broadcast addresses of the interfaces.

### deprecated

Marks the address as a deprecated address. Addresses marked as deprecated will not be used as source address for outbound packets unless either there are no other addresses available on this interface or the application has bound to this address explicitly. The status display shows DEPRECATED as part of flags.

### -deprecated

Marks the address as not deprecated.

### destination *dest\_address*

Set the destination address for a point-to point interface.

### dhcp

This option is an alias for option `auto-dhcp`

### down

Mark an interface "down". When an interface is marked "down", the system does not attempt to transmit messages through that interface. If possible, the interface is reset to disable reception as well. This action does not automatically disable routes using the interface.

### encr\_auth\_algs *authentication algorithm*

For a tunnel, enable IPsec ESP with the authentication algorithm specified. It can be either a number or an algorithm name, including any or none, to indicate no algorithm preference. If an ESP encryption algorithm is specified but the authentication algorithm is not, the default value for the ESP authentication algorithm will be any.

### encr\_algs *encryption algorithm*

For a tunnel, enable IPsec ESP with the encryption algorithm specified. It can be either a number or an algorithm name. Note that all IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify the value of `encr_alg` as none. If an ESP authentication algorithm is specified, but the encryption algorithm is not, the default value for the ESP encryption will be null.

### -failover

Mark the address as a non-failover address. Addresses marked this way will not failover when the interface fails. Status display shows "NOFAILOVER" as part of flags.

### failover

Mark the address as a failover address. This address will failover when the interface fails. Status display does not show "NOFAILOVER" as part of flags.

`group [ name | "" ]`

Insert the interface in the multipathing group specified by *name*. To delete an interface from a group, use a null string "". When invoked on the logical interface with id zero, the status display shows the group name.

`index n`

Change the interface index for the interface. The value of *n* must be an interface index (*if\_index*) that is not used on another interface. *if\_index* will be a non-zero positive number that uniquely identifies the network interface on the system.

`metric n`

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable; metrics are counted as addition hops to the destination network or host.

`modinsert mod_name@pos`

Insert a module with name *mod\_name* to the stream of the device at position *pos*. The position is relative to the stream head. Position 0 means directly under stream head.

Based upon the example in the `modlist` option, use the following command to insert a module with name `ipqos` under the `ip` module and above the `firewall` module:

```
example% ifconfig hme0 modinsert ipqos@2
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 ipqos
3 firewall
4 hme
```

`modlist`

List all the modules in the stream of the device.

The following example lists all the modules in the stream of the device:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 firewall
4 hme
```

`modremove mod_name@pos`

Remove a module with name *mod\_name* from the stream of the device at position *pos*. The position is relative to the stream head.

## ifconfig(1M)

Based upon the example in the `modinsert` option, use the following command to remove the firewall module from the stream after inserting the `ipqos` module:

```
example% ifconfig hme0 modremove firewall@3
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig hme0 modlist
0 arp
1 ip
2 ipqos
3 hme
```

Note that the core IP stack modules, for example, `ip` and `tun` modules, cannot be removed.

### `mtu n`

Set the maximum transmission unit of the interface to *n*. For many types of networks, the `mtu` has an upper limit, for example, 1500 for Ethernet.

### `netmask mask`

For IPv4 only. Specify how much of the address to reserve for subdividing networks into subnetworks. The mask includes the network part of the local address and the subnet part, which is taken from the host field of the address. The mask contains 1's for the bit positions in the 32-bit address which are to be used for the network and subnet parts, and 0's for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

1. with a single hexadecimal number with a leading 0x,
2. with a dot-notation address,
3. with a "+" (plus sign) address, or
4. with a pseudo host name/pseudo network name found in the network database `networks(4)`.

If a "+" (plus sign) is given for the netmask value, the mask is looked up in the `netmasks(4)` database. This lookup finds the longest matching netmask in the database by starting with the interface's IPv4 address as the key and iteratively masking off more and more low order bits of the address. This iterative lookup ensures that the `netmasks(4)` database can be used to specify the netmasks when variable length subnetmasks are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the `hosts` or `networks` database. Names are looked up by first using `gethostbyname(3NSL)`. If not found there, the names are looked up in `getnetbyname(3SOCKET)`. These interfaces may in turn use `nsswitch.conf(4)` to determine what data store(s) to use to fetch the actual value.

For both `inet` and `inet6`, the same information conveyed by *mask* can be specified as a *prefix\_length* attached to the *address* parameter.

`nud`  
Enables the neighbor unreachability detection mechanism on a point-to-go interface.

`-nud`  
Disables the neighbor unreachability detection mechanism on a point-to-go interface.

`plumb`  
Open the device associated with the physical interface name and set up the streams needed for IP to use the device. When used with a logical interface name, this command is used to create a specific named logical interface. An interface must be separately plumbed for use by IPv4 and IPv6. The *address\_family* parameter controls whether the `ifconfig` command applies to IPv4 or IPv6.

Before an interface has been plumbed, , the interface will not show up in the output of the `ifconfig -a` command.

`private`  
Tells the `in.routed` routing daemon that the interface should not be advertised.

`-private`  
Specify unadvertised interfaces.

`removeif address`  
Remove the logical interface on the physical interface specified that matches the *address* specified.

`set`  
Set the *address*, *prefix\_length* or both, for an interface.

`standby`  
Marks the physical interface as a standby interface. If the interface is marked `STANDBY` and is part of the multipathing group, the interface will not be selected to send out packets unless some other interface in the group has failed and the network access has been failed over to this standby interface.

The status display shows "`STANDBY, INACTIVE`" indicating that that the interface is a standby and is also inactive. `IFF_INACTIVE` will be cleared when some other interface belonging to the same multipathing group fails over to this interface. Once a failback happens, the status display will return to `INACTIVE`.

`-standby`  
Turns off standby on this interface.

`subnet`  
Set the subnet *address* for an interface.

`tdst tunnel_dest_address`  
Set the destination address of a tunnel. The address should not be the same as the *dest\_address* of the tunnel, because no packets leave the system over such a tunnel.

## ifconfig(1M)

### trailers

This flag previously caused a nonstandard encapsulation of `inet` packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored.

### -trailers

Disable the use of a "trailer" link level encapsulation.

### tsrc *tunnel\_src\_address*

Set the source address of a tunnel. This is the source address on an outer encapsulating IP header. It must be an address of another interface already configured using `ifconfig`.

### unplumb

Close the device associated with this physical interface name and any streams that `ifconfig` set up for IP to use the device. When used with a logical interface name, the logical interface is removed from the system. After this command is executed, the device name will no longer appear in the output of `ifconfig -a`.

### up

Mark an interface "up". This happens automatically when setting the first address on an interface. The `up` option enables an interface after an `ifconfig down`, which reinitializes the hardware.

### xmit

Enable an interface to transmit packets. This is the default behavior when the interface is up.

### -xmit

Disable transmission of packets on an interface. The interface will continue to receive packets.

**OPERANDS** The *interface* operand, as well as address parameters that affect it, are described below.

### *interface*

A string of the form, *name physical-unit*, for example, `le0` or `ie1`; or of the form *name physical-unit : logical-unit*, for example, `le0 : 1`; or of the form `ip.tunN`, for tunnels.

If the interface name starts with a dash (-), it is interpreted as a set of options which specify a set of interfaces. In such a case, `-a` must be part of the options and any of the additional options below can be added in any order. If one of these interface names is given, the commands following it are applied to all of the interfaces that match.

- a Apply the commands to all interfaces in the system.
- d Apply the commands to all "down" interfaces in the system.

- D Apply the commands to all interfaces not under DHCP (Dynamic Host Configuration Protocol) control.
- u Apply the commands to all "up" interfaces in the system.
- 4 Apply the commands to all IPv4 interfaces.
- 6 Apply the commands to all IPv6 interfaces.

*address\_family*

The address family is specified by the *address\_family* parameter. The `ifconfig` command currently supports the following families: `ether`, `inet`, and `inet6`. If no address family is specified, the default is `inet`.

*address*

For the IPv4 family (`inet`), the *address* is either a host name present in the host name data base (see `hosts(4)`) or in the Network Information Service (NIS) map `hosts`, or an IPv4 address expressed in the Internet standard "dot notation".

For the IPv6 family (`inet6`), the *address* is either a host name present in the host name data base (see `ipnodes(4)`) or in the Network Information Service (NIS) map `ipnode`, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as `x::x::x::x::x` where `x` is a hexadecimal number between 0 and `FFFF`.

For the `ether` address family, the address is an Ethernet address represented as `x:x:x: x:x:x` where `x` is a hexadecimal number between 0 and `FF`.

Some, though not all, of the Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for a definition of the locally administered address space. The use of interface groups should be restricted to those cards with their own addresses (see `INTERFACE GROUPS`).

*prefix\_length*

For the IPv4 and IPv6 families (`inet` and `inet6`), the *prefix\_length* is a number between 0 and the number of bits in the address. For `inet`, the number of bits in the address is 32; for `inet6`, the number of bits in the address is 128. The *prefix\_length* denotes the number of leading set bits in the netmask.

## ifconfig(1M)

|                            |                                                                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dest_address</i>        | If the <i>dest_address</i> parameter is supplied in addition to the <i>address</i> parameter, it specifies the address of the correspondent on the other end of a point-to-point link.                                                               |
| <i>tunnel_dest_address</i> | An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the <i>tunnel_dest_address</i> being configured. |
| <i>tunnel_src_address</i>  | As address that is attached to an already configured interface that has been configured "up" with <code>ifconfig</code> .                                                                                                                            |

### LOGICAL INTERFACES

Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form *driver-name physical-unit-number*, while logical interfaces have names of the form *driver-name physical-unit-number : logical-unit-number*. A physical interface is configured into the system using the `plumb` command. For example:

```
example% ifconfig le0 plumb
```

Once a physical interface has been "plumbed", logical interfaces associated with the physical interface can be configured by separate `plumb` or `addif` options to the `ifconfig` command.

```
example% ifconfig le0:1 plumb
```

allocates a specific logical interface associated with the physical interface `le0`. The command

```
example% ifconfig le0 addif 192.9.200.1/24 up
```

allocates the next available logical unit number on the `le0` physical interface and assigns an *address* and *prefix\_length*.

A logical interface can be configured with parameters (*address*, *prefix\_length*, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with an existing and "up" physical interface. So, for example, the logical interface `le0:1` can only be configured after the physical interface `le0` has been plumbed.

To delete a logical interface, use the `unplumb` or `removeif` options. For example,

```
example% ifconfig le0:1 down unplumb
```

**INTERFACE GROUPS**

will delete the logical interface `le0:1`.

If a physical interface shares an IP prefix with another interface, these interfaces are collected into an interface group. IP uses an interface group to rotate source address selection when the source address is unspecified, and in the case of multiple physical interfaces in the same group, to scatter traffic across different IP addresses on a per-IP-destination basis. See `netstat(1M)` for per-IP-destination information.

This feature may be enabled by using `ndd(1M)`.

One can also use the `group` keyword to form a multipathing group. When multipathing groups are used, the functionality of the `interface group` is subsumed into the functionality of the multipathing group. A multipathing group provides failure detection and repair detection for the interfaces in the group. See `in.mpathd(1M)` and *System Administration Guide, Volume 3*.

The interface groups formed using `ndd(1M)` will be made obsolete in the future. Accordingly, it is advisable to use form multipathing groups using the `group` keyword.

**CONFIGURING IPv6 INTERFACES**

When an IPv6 physical interface is plumbed and configured “up” with `ifconfig`, it is automatically assigned an IPv6 link-local address for which the last 64 bits are calculated from the MAC address of the interface.

```
ifconfig le0 inet6 plumb up
```

The following example shows that the link-local address has a prefix of `fe80::/10`.

```
example% ifconfig le0 inet6
le0: flags=2000841<UP, RUNNING, MULTICAST, IPv6>
 mtu 1500 index 2
 inet6 fe80::a00:20ff:fe8e:f3ad/10
```

If an advertising IPv6 router exists on the link advertising prefixes, then the newly plumbed IPv6 interface will autoconfigure logical interface(s) depending on the prefix advertisements. For example, for prefix advertisements `fec0:0:0:55::/64` and `3ff0:0:0:55::/64`, the autoconfigured interfaces will look like:

```
le0:1: flags=2080841<UP, RUNNING, MULTICAST, ADDRCONF, IPv6>
 mtu 1500 index 2
 inet6 fec0::55:a00:20ff:fe8e:f3ad/64
le0:2: flags=2080841<UP, RUNNING, MULTICAST, ADDRCONF, IPv6>
 mtu 1500 index 2
 inet6 3ff0::55:a00:20ff:fe8e:f3ad/64
```

Even if there are no prefix advertisements on the link, you can still assign site-local and global addresses manually, for example:

```
example% ifconfig le0 inet6 addif fec0::55:a00:20ff:fe8e:f3ad/64 up
example% ifconfig le0 inet6 addif 3ff0::55:a00:20ff:fe8e:f3ad/64 up
```

## ifconfig(1M)

### Configuring IPv6/IPv4 tunnels

To configure boot-time defaults for the interface `le0`, place the following entries in the `/etc/hostname6.le0` file:

```
addif fec0::55:a00:20ff:fe8e:f3ad/64 up
addif 3ff0::55:a00:20ff:fe8e:f3ad/64 up
```

Link-local addresses are only used for on-link communication and are not visible to other subnets.

An IPv6 over IPv4 tunnel interface can send and receive IPv6 packets encapsulated in an IPv4 packet. Create tunnels at both ends pointing to each other. IPv6 over IPv4 tunnels require the tunnel source and tunnel destination IPv4 and IPv6 addresses. Solaris 8 supports both automatic and configured tunnels. For automatic tunnels, an IPv4-compatible IPv6 address is used. The following demonstrates auto-tunnel configuration:

```
example% ifconfig ip.atun0 inet6 plumb
example% ifconfig ip.atun0 inet6 tsrc <IPv4-address> \
::<IPv4 address>/96 up
```

where `IPv4-address` is the IPv4 address of the interface through which the tunnel traffic will flow, and `IPv4-address, ::<IPv4-address>`, is the corresponding IPv4-compatible IPv6 address.

The following is an example of a configured tunnel:

```
example% ifconfig ip.tun0 inet6 plumb tsrc <my-ipv4-address> \
tdst <peer-ipv4-address> up
```

This creates a configured tunnel between `my-ipv4-address` and `peer-ipv4-address` with corresponding link-local addresses. For tunnels with global or site-local addresses, the logical tunnel interfaces need to be configured in the following form:

```
ifconfig ip.tun0 inet6 addif <my-v6-address> <peer-v6-address> up
```

For example,

```
example% ifconfig ip.tun0 inet6 plumb tsrc 109.146.85.57 \
tdst 109.146.85.212 up
example% ifconfig ip.tun0 inet6 addif 2::45 2::46 up
```

To show all IPv6 interfaces that are up and configured:

```
example% ifconfig -au6
ip.tun0: flags=2200851<UP, POINTOPOINT, RUNNING, MULTICAST, NONUD, IPv6>
mtu 1480 index 3
inet tunnel src 109.146.85.57 tunnel dst 109.146.85.212
inet6 fe80::6d92:5539/10 --> fe80::6d92:55d4
```

```
ip.tun0:1: flags=2200851<UP, POINTOPOINT, RUNNING, MULTICAST, NONUD, IPv6>
 mtu 1480 index 3
 inet6 2::45/128 --> 2::46
```

**EXAMPLES** **EXAMPLE 1** Using the `ifconfig` Command

If your workstation is not attached to an Ethernet, the `le0` interface should be marked "down" as follows:

```
example% ifconfig le0 down
```

**EXAMPLE 2** Printing Addressing Information

To print out the addressing information for each interface, use the following command:

```
example% ifconfig -a
```

**EXAMPLE 3** Resetting the Broadcast Address

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

**EXAMPLE 4** Changing the Ethernet Address

To change the Ethernet address for interface `le0`, use the following command:

```
example% ifconfig le0 ether aa:1:2:3:4:5
```

**EXAMPLE 5** Configuring an IP-in-IP Tunnel

To configure an IP-in-IP tunnel, first plumb it with the following command:

```
example% ifconfig ip.tun0 plumb
```

Then configure it as a point-to-point interface, supplying the tunnel source and the tunnel destination:

```
example% ifconfig ip.tun0 myaddr mydestaddr tsrc another_myaddr \
 tdst a_dest_addr up
```

Tunnel security properties must be configured on one invocation of `ifconfig`:

```
example% ifconfig ip.tun0 encr_auth_algs md5 encr_algs 3des
```

## ifconfig(1M)

### EXAMPLE 6 Requesting a Service Without Algorithm Preference

To request a service without any algorithm preferences, specify any:

```
example% ifconfig ip.tun0 encr_auth_algs any encr_algs any
```

### EXAMPLE 7 Disabling All Security

To disable all security, specify any security service with none as the algorithm value:

```
example% ifconfig ip.tun0 auth_algs none
```

or

```
example% ifconfig ip.tun0 encr_algs none
```

**DIAGNOSTICS** `ifconfig` sends messages that indicate if:

- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

**NOTES** It is recommended that the names `broadcast`, `down`, `private`, `trailers`, `up`, and the other possible option names not be selected when choosing host names. Choosing any one of these names as host names will cause bizarre problems that can be extremely difficult to diagnose.

## if\_mpadm(1M)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                |                                                                       |                                |                                                                                                                                                                                                                         |

| <b>NAME</b>                    | if_mpadm – change operational status of interfaces within a multipathing group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>                | <pre>/usr/sbin/if_mpadm -d interface_name /usr/sbin/if_mpadm -r interface_name</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b>             | <p>Use the <code>if_mpadm</code> utility to change the operational status of interfaces that are part of a multipathing group. If the interface is operational, you can use <code>if_mpadm -d</code> to detach or off-line the interface. If the interface is off-lined, use <code>if_mpadm -r</code> to revert it to its original state.</p> <p>When a network interface is off-lined, all network access fails over to a different interface in the multipathing group. Any addresses that do not failover are brought down. Network access includes unicast, broadcast, and multicast for IPv4 and unicast and multicast for IPv6. Addresses marked with <code>IFF_NOFAILOVER</code> do not failover; they are marked down. After an interface is off-lined, the system will not use the interface for any outbound or inbound traffic, and the interface can be safely removed from the system without any loss of network access.</p> <p>The <code>if_mpadm</code> utility can be applied only to interfaces that are part of a multipathing group.</p> |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>OPTIONS</b>                 | <p>The <code>if_mpadm</code> utility supports the following options:</p> <table><tr><td><code>-d interface_name</code></td><td>Detach or off-line the interface specified by <i>interface_name</i>.</td></tr><tr><td><code>-r interface_name</code></td><td>Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i>. Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <code>-d interface_name</code> | Detach or off-line the interface specified by <i>interface_name</i> . | <code>-r interface_name</code> | Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i> . Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail. |
| <code>-d interface_name</code> | Detach or off-line the interface specified by <i>interface_name</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <code>-r interface_name</code> | Reattach or undo the previous detach or off-line operation on the interface specified by <i>interface_name</i> . Unless the <code>-d</code> option was used to detach or off-line the interface, this option will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |                                                                       |                                |                                                                                                                                                                                                                         |
| <b>EXAMPLES</b>                | <p><b>EXAMPLE 1</b> Detaching an Interface</p> <p>Use the following command to off-line or detach the interface. All network access will failback to <code>hme0</code> from another interface in the group.</p> <pre>example% if_mpadm -d hme0</pre> <p><b>EXAMPLE 2</b> Reattaching an Off-line Interface</p> <p>Use the following command to undo the previous operation. Network access will failback over to <code>hme0</code> from an interface in the same multipathing group.</p> <pre>example% if_mpdadm -r hme0</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                |                                                                       |                                |                                                                                                                                                                                                                         |

#### DIAGNOSTICS

off-line failed as there is no other functional interface available in the multipathing group for failing over the network access.

This message means that other interfaces in the group are failed over already or the multipathing configuration was not suitable for completing a failover.

off-line cannot be undone as failback has been disabled.

FAILBACK is set to "no" in /etc/default/mpathd.

off-line cannot be undone because multipathing configuration is not consistent across all the interfaces in the group.

This message means that some interfaces in the multipathing group are not configured consistently with other interfaces in the group, for example, one of the interfaces in the group does not have an IFF\_NOFAILOVER address.

| <b>NAME</b>        | ifparse – parse ifconfig command line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/sbin/ifparse [-fs] addr_family commands</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | Use the ifparse command to parse the ifconfig(1M) command line options and output substrings, one per line, as appropriate. If no options are specified, ifparse returns the entire ifconfig command line as a series of substrings, one per line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | The ifparse command supports the following options:<br><br>-f        Lists only substrings of the ifconfig command line that are relevant to IP network multipath failover<br><br>-s        Lists only substrings of the ifconfig command line that are not relevant to IP network multipath failover                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPERANDS</b>    | The ifparse command <i>does not</i> support the <i>interface</i> operand of the ifconfig command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Parsing Command Line Options Relevant to Failover</p> <p>The following example shows the use of the ifparse command to parse the command line options relevant to IP network multipath failover:</p> <pre>example# ifparse -f inet 1.2.3.4 up group one addif 1.2.3.5 -failover up set 1.2.3.4 up</pre> <p><b>EXAMPLE 2</b> Parsing Command Line Options That Are Not Relevant to Failover</p> <p>The following example shows the use of the ifparse command to parse the command line options that are not relevant to IP network multipath failover:</p> <pre>example# ifparse -s inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one addif 1.2.3.5 -failover up</pre> <p><b>EXAMPLE 3</b> Parsing the Command Line For All Options</p> <p>The following example shows the use of the ifparse command to parse the command line for all ifconfig options:</p> <pre>example# ifparse inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one set 1.2.3.4 up addif 1.2.3.5 -failover up</pre> |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsr         |
| Stability Level | Obsolete        |

**SEE ALSO** `ifconfig(1M)`, `attributes(5)`

**DIAGNOSTICS** `usage: -fs <addr_family> <commands>`  
 This message indicates an invalid command line.

`ifparse: Not enough space`  
 This message indicates insufficient memory.

`ifparse: dhcp not supported for inet6`  
 DHCP operations are not supported for the `inet6` address family.

`ifparse: Operation <operation> not supported for <addr_family>`  
 Most operations cannot be used with all address families. For example, the `broadcast` operation is not supported on the `inet6` address family.

`ifparse: no argument for <operation>`  
 Some operations, for example `broadcast`, require an argument.

**NOTES** The `ifparse` command is classified as an obsolete interface. It will likely be removed in a future release. You should not develop applications that depend upon this interface.

in.comsat(1M)

**NAME** | in.comsat, comsat – biff server

**SYNOPSIS** | `/usr/sbin/in.comsat`

**DESCRIPTION** | comsat is the server process which listens for reports of incoming mail and notifies users who have requested to be told when mail arrives. It is invoked as needed by inetd(1M), and times out if inactive for a few minutes.

comsat listens on a datagram port associated with the `biff` service specification (see `services(4)`) for one line messages of the form

*user@mailbox-offset*

If the *user* specified is logged in to the system and the associated terminal has the owner execute bit turned on (by a `biff y`), the *offset* is used as a seek offset into the appropriate mailbox file, and the first 7 lines or 560 characters of the message are printed on the user's terminal. Lines which appear to be part of the message header other than the `From`, `To`, `Date`, or `Subject` lines are not printed when displaying the message.

**FILES** | `/var/adm/utmpx` user access and administration information

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `inetd(1M)`, `services(4)`, `attributes(5)`

**NOTES** | The message header filtering is prone to error.

| <b>DESCRIPTION</b> | <p>in.dhcpd is a daemon that responds to Dynamic Host Configuration Protocol (DHCP) requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that runs as a background process. It must be run as root. The daemon has two run modes, DHCP server (with optional BOOTP compatibility mode) and BOOTP relay agent mode.</p> <p>The first line in the <i>SYNOPSIS</i> section illustrates the options available in the DHCP/BOOTP server mode. The second line in the <i>SYNOPSIS</i> section illustrates the options available when the daemon is run in BOOTP relay agent mode.</p> <p>The DHCP and BOOTP protocols are used to provide configuration parameters to Internet hosts. Client machines are allocated their IP addresses as well as other host configuration parameters through this mechanism.</p> <p>The DHCP/BOOTP daemon manages two types of DHCP data tables: the dhcptab configuration table and the DHCP network tables.</p> <p>See dhcptab(4) regarding the dhcptab configuration table and dhcp_network(4) regarding the DHCP network tables.</p> <p>The dhcptab contains macro definitions defined using a termcap-like syntax which permits network administrators to define groups of DHCP configuration parameters to be returned to clients. However, a DHCP/BOOTP server always returns hostname, network broadcast address, network subnet mask, and IP maximum transfer unit (MTU) if requested by a client attached to the same network as the server machine. If those options have not been explicitly configured in the dhcptab, in.dhcpd returns reasonable default values.</p> <p>The dhcptab is read at startup, upon receipt of a SIGHUP signal, or periodically as specified by the -t option. A SIGHUP (sent using the command <code>kill -HUP in.dhcpd</code>) causes the DHCP/BOOTP daemon to reread the dhcptab within an interval from 0-60 seconds (depending on where the DHCP daemon is in its polling cycle). For busy servers, users should run <code>/etc/init.d/dhcp stop</code>, followed by <code>/etc/init.d/dhcp start</code> to force the dhcptab to be reread.</p> <p>The DHCP network tables contain mappings of client identifiers to IP addresses. These tables are named after the network they support and the datastore used to maintain them.</p> <p>The DHCP network tables are consulted during runtime. A client request received from a network for which no DHCP network table exists is ignored.</p> |

## in.dhcpd(1M)

This command may change in future releases of Solaris software. Scripts, programs, or procedures that use this command might need modification when upgrading to future Solaris software releases. The command line options provided with the `in.dhcpd` daemon are used only for the current session, and include only some of the server options you can set. The `dhcpsvc.conf(4)` contains all the server default settings, and can be modified by using the `dhcpmgr` utility. See `dhcpsvc.conf(4)` and `dhcpmgr(1M)` for more details.

### OPTIONS

The following options are supported:

`-b automatic | manual`

This option enables BOOTP compatibility mode, allowing the DHCP server to respond to BOOTP clients. The option argument specifies whether the DHCP server should automatically allocate permanent lease IP addresses to requesting BOOTP clients if the clients are not registered in the DHCP network tables (`automatic`) or respond only to BOOTP clients who have been manually registered in the DHCP network tables (`manual`). This option only affects DHCP server mode.

`-d`

Debugging mode. The daemon remains as a foreground process, and displays verbose messages as it processes DHCP and/or BOOTP datagrams. Messages are displayed on the current TTY. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-h relay_hops`

Specifies the maximum number of relay agent hops that can occur before the daemon drops the DHCP/BOOTP datagram. The default number of relay agent hops is 4. This option affects both DHCP/BOOTP server mode and BOOTP relay agent mode.

`-i interface, . . .`

Selects the network interfaces that the daemon should monitor for DHCP/BOOTP datagrams. The daemon ignores DHCP/BOOTP datagrams on network interfaces not specified in this list. This option is only useful on machines that have multiple network interfaces. If this option is not specified, then the daemon listens for DHCP/BOOTP datagrams on all network interfaces. The option argument consists of a comma-separated list of interface names. It affects both DHCP/BOOTP server and BOOTP relay agent run modes.

`-l syslog_local_facility`

The presence of this option turns on transaction logging for the DHCP server or BOOTP relay agent. The value specifies the `syslog` local facility (an integer from 0 to 7 inclusive) the DHCP daemon should use for tagging the transactions. Using a facility separate from the `LOG_DAEMON` facility allows the network administrator to capture these transactions separately from other DHCP daemon events for such purposes as generating transaction reports. See `syslog(3C)`, for details about local facilities. Transactions are logged using a record with 9 space-separated fields as follows:

1. Protocol:

Relay mode: "BOOTP"  
 Server mode: "BOOTP" or "DHCP" based upon client type.

2. Type:

Relay mode: "RELAY-CLNT", "RELAY-SRVR"  
 Server mode: "ASSIGN", "EXTEND", "RELEASE",  
 "DECLINE", "INFORM", "NAK" "ICMP-ECHO."

3. Transaction time: absolute time in seconds (unix time)

4. Lease time:

Relay mode: Always 0.  
 Server mode: 0 for ICMP-ECHO events, absolute time in seconds (unix time) otherwise

5. Source IP address: Dotted Internet form

Relay mode: Relay interface IP on RELAY-CLNT,  
 INADDR\_ANY on RELAY-SRVR.  
 Server mode: Client IP.

6. Destination IP address: Dotted Internet form

Relay mode: Client IP on RELAY-CLNT, Server IP on  
 RELAY-SRVR.  
 Server mode: Server IP.

7. Client Identifier: Hex representation (0-9, A-F)

Relay mode: MAC address  
 Server mode: BOOTP - MAC address; DHCP - client id

8. Vendor Class identifier (white space converted to periods (.)).

Relay mode: Always "N/A"  
 Server mode: Vendor class ID tokenized by  
 converting white space characters  
 to periods (.)

9. MAC address: Hex representation (0-9, A-F)

Relay mode: MAC address  
 Server mode: MAC address

The format of this record is subject to change between releases.

Transactions are logged to the console if daemon is in debug mode (-d).

Logging transactions impact daemon performance.

## in.dhcpd(1M)

It is suggested that you manage log file size periodically using a script run by `cron(1M)` and sending `syslogd(1M)` a `SIGHUP` signal. You could, for example, clone `/usr/lib/newsyslog` and alter it to match your DHCP logging requirements.

-n

Disable automatic duplicate IP address detection. When this option is specified, the DHCP server does not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.

-o *DHCP\_offer\_time*

Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option affects only DHCP server mode.

-r *IP\_address | hostname, . . .*

This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP tables are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the `BROADCAST` flag described in RFC 1542. A BOOTP relay agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the `netmasks` database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client's network. See `netmasks(4)` for the format and use of this database.

-t *dhcptab\_rescan\_interval*

Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the `dhcptab` information. Typically, you would use this option if the changes to the `dhcptab` are relatively frequent. Once the contents of the `dhcptab` have stabilized, you can turn off this option to avoid needless reinitialization of the server.

-v

Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the `syslogd` facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

**EXAMPLES****EXAMPLE 1** Starting a DHCP Server in BOOTP Compatibility Mode

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server's table; limits the server's attention to incoming datagrams on network devices `le2` and `tr0`; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules `dhcptab` rescans to occur every 10 minutes:

```
in.dhcpd -i le2,tr0 -h 2 -o 15 -t 10 -b automatic
```

**EXAMPLE 2** Starting the Daemon in BOOTP Relay Agent Mode

The following command starts the daemon in BOOTP relay agent mode, registering the hosts `bladerunner` and `10.0.0.5` as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
in.dhcpd -d -v -h 5 -r bladerunner,10.0.0.5
```

**FILES**

```
/etc/inet/dhcpsvc.conf
/etc/init.d/dhcp
/etc/init/hosts
/usr/lib/inet/dhcp/nsu/rfc2136.so.1
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWdhcsu       |
| Interface Stability | Evolving        |

| <b>NAME</b>        | inetd – Internet services daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>inetd</b> [-d] [-s] [-t] [-r <i>count interval</i> ] [ <i>configuration-file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>inetd is the server process for the Internet standard services. It is usually started up at system boot time. The <i>configuration-file</i> lists the services that inetd is to provide. If no <i>configuration-file</i> is given on the command line, inetd reads its configuration information from the file <code>/etc/inetd.conf</code>. See <code>inetd.conf(4)</code> for more information on the format of this file. inetd listens for service requests on the TCP or UDP ports associated with each of the service listed in the configuration file. When a request arrives, inetd executes the server program associated with the service.</p> <p>A service can be configured to be "wait" wait-status, in which case, inetd waits for the server process to exit before starting a second server process. RPC services can also be started by inetd.</p> <p>inetd provides a number of simple Internet services internally. These include <code>echo</code>, <code>discard</code>, <code>chargen</code> (character generator), <code>daytime</code> (human-readable time), and <code>time</code> (machine-readable time, in the form of the number of seconds since midnight, January 1, 1900).</p> <p>inetd rereads its <i>configuration-file</i> once when it is started and again whenever it receives a hangup signal, <code>SIGHUP</code>. New services can be activated and existing services can be deleted or modified by editing the <i>configuration-file</i>, then sending inetd a <code>SIGHUP</code> signal.</p> <p>Then inetd reads the <i>configuration-file</i> and attempts to <code>bind()</code> to the service to start listening to it. That attempt may fail if another standalone server or "wait" wait-status server started by inetd is already listening for this service. inetd will defer implementing the newly read configuration for that service and will attempt periodically to start listening, after logging an error on console. The retry interval is currently 10 minutes.</p> |
| <b>OPTIONS</b>     | <p>-d       Runs inetd in the foreground and enables debugging output.</p> <p>-s       Allows you to run inetd "stand-alone," outside the Service Access Facility ("SAF"). If the -s option is omitted, inetd will attempt to contact the service access controller ("SAC") and will exit if SAC is not already running. See <code>sac(1M)</code></p> <p>-t       Instructs inetd to trace the incoming connections for all of its TCP services. It does this by logging the client's IP address and TCP port number, along with the name of the service, using the <code>syslog(3C)</code> facility. UDP services can not be traced. When tracing is enabled, inetd uses the <code>syslog</code> facility code "daemon" and "notice" priority level.</p> <p>-r       Allows inetd to detect and then suspend "broken" connectionless datagram services servers, for example, UDP, and RPC/CLTS. Without this</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## inetd(1M)

detection, a buggy server that fails before consuming the service request will be continuously restarted and will tax system resources too much. The `-r` flag has the form:

`-r count intervalcount` and `interval` are decimal numbers that represent the maximum `count` of invocations per `interval` of seconds a service may be started before the service is considered "broken."

Once considered "broken," a server is suspended for ten minutes. After ten minutes, `inetd` again enables service, hoping the server behaves correctly.

If the `-r` flag is not specified, `inetd` behaves as though `-r40 60` was specified.

**OPERANDS** `configuration-file` Lists the services `inetd` is to provide.

**EXIT STATUS** `inetd` does not return an exit status.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `in.ftpd(1M)`, `in.rexecd(1M)`, `in.rshd(1M)`, `in.tftpd(1M)`, `sac(1M)`, `syslog(3C)`, `inetd.conf(4)`, `attributes(5)`

**WARNINGS** Do not configure `udp` services as `nowait`. This will cause a race condition where the `inetd` program selects on the socket and the server program reads from the socket. Many server programs will be forked and performance will be severely compromised.

**NOTES** For RPC services, `inetd` listens on all the transports (not only `tcp` and `udp`) as specified for each service in the `inetd.conf(4)` file.

| <b>NAME</b>                   | in.fingerd, fingerd – remote user information server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                             |                                  |                          |                       |                               |                   |                           |               |                              |                  |

| <b>SYNOPSIS</b>               | <code>/usr/sbin/in.fingerd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                             |                                  |                          |                       |                               |                   |                           |               |                              |                  |
| <b>DESCRIPTION</b>            | <p>fingerd implements the server side of the Name/Finger protocol, specified in <i>RFC 742</i>. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.</p> <p>fingerd waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to <code>finger(1)</code>, prepended with <code>-s</code>. <code>fingerd</code> closes its connections as soon as the output is finished.</p> <p>You must invoke <code>fingerd</code> from <code>inetd</code>. See <code>inetd(1M)</code> for more information.</p> |                             |                                  |                          |                       |                               |                   |                           |               |                              |                  |

| <b>NOTES</b>                  | Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which will foul up the command line interpretation. <code>fingerd</code> should be taught to filter out IAC's and perhaps even respond negatively (IAC will not) to all option commands received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                             |                                  |                          |                       |                               |                   |                           |               |                              |                  |

| <b>DESCRIPTION</b> | <p>infocmp compares a binary <code>terminfo</code> entry with other <code>terminfo</code> entries, rewrites a <code>terminfo</code> description to take advantage of the <code>use=</code> <code>terminfo</code> field, or prints out a <code>terminfo</code> description from the binary file (<code>term</code>) in a variety of formats. It displays boolean fields first, then numeric fields, followed by the string fields. If no options are specified and zero, or one <code>termname</code> is specified, the <code>-I</code> option is assumed. If more than one <code>termname</code> is specified, the <code>-d</code> option is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The <code>-d</code>, <code>-c</code>, and <code>-n</code> options can be used for comparisons. <code>infocmp</code> compares the <code>terminfo</code> description of the first terminal <code>termname</code> with each of the descriptions given by the entries for the other terminal's <code>termname</code>. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: <code>F</code> for boolean variables, <code>-1</code> for integer variables, and <code>NULL</code> for string variables.</p> <ul style="list-style-type: none"><li><code>-d</code> Produce a list of each capability that is different between two entries. This option is useful to show the difference between two entries, created by different people, for the same or similar terminals.</li><li><code>-c</code> Produce a list of each capability that is common between two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the <code>-u</code> option is worth using.</li><li><code>-n</code> Produce a list of each capability that is in neither entry. If no <code>termname</code> is given, the environment variable <code>TERM</code> will be used for both of the <code>termnames</code>. This can be used as a quick check to see if anything was left out of a description.</li></ul> <p>The <code>-I</code>, <code>-L</code>, and <code>-C</code> options will produce a source listing for each terminal named.</p> <ul style="list-style-type: none"><li><code>-I</code> Use the <code>terminfo</code> names.</li><li><code>-L</code> Use the long <code>C</code> variable name listed in <code>&lt;term.h&gt;</code>.</li><li><code>-C</code> Use the <code>termcap</code> names. The source produced by the <code>-C</code> option may be used directly as a <code>termcap</code> entry, but not all of the parameterized strings may be changed to the <code>termcap</code> format. <code>infocmp</code> will attempt to convert most of the parameterized information, but anything not converted will be plainly marked in the output and commented out. These should be edited by hand.</li><li><code>-r</code> When using <code>-C</code>, put out all capabilities in <code>termcap</code> form.</li></ul> <p>If no <code>termname</code> is given, the environment variable <code>TERM</code> will be used for the terminal name.</p> |

All padding information for strings will be collected together and placed at the beginning of the string where `termcap` expects it. Mandatory padding (padding information with a trailing `'/'`) will become optional.

All `termcap` variables no longer supported by `terminfo`, but are derivable from other `terminfo` variables, will be displayed. Not all `terminfo` capabilities will be translated; only those variables which were part of `termcap` will normally be displayed. Specifying the `-r` option will take off this restriction, allowing all capabilities to be displayed in `termcap` form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because `termcap` strings are not as flexible, it is not always possible to convert a `terminfo` string capability into an equivalent `termcap` format. A subsequent conversion of the `termcap` file back into `terminfo` format will not necessarily reproduce the original `terminfo` source.

Some common `terminfo` parameter sequences, their `termcap` equivalents, and some terminal types which commonly have such sequences, are:

| terminfo                                   | termcap                                  | Representative Terminals |
|--------------------------------------------|------------------------------------------|--------------------------|
| <code>%p1%c</code>                         | <code>%. adm</code>                      |                          |
| <code>%p1%d</code>                         | <code>%d hp, ANSI standard, vt100</code> |                          |
| <code>%p1%'x'%'%+c</code>                  | <code>%+x concept</code>                 |                          |
| <code>%i</code>                            | <code>%i ANSI standard, vt100</code>     |                          |
| <code>%p1%?'x'%'&gt;%t%p1%'y'%'%+%;</code> | <code>%&gt;xy concept</code>             |                          |
| <code>%p2</code>                           | <code>is printed before %p1 %r hp</code> |                          |

`-u` Produce a `terminfo` source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals' *termnames*. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with `use=` fields for the other terminals. In this manner, it is possible to retrofit generic `terminfo` entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using `infocmp` will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (`@`) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value is displayed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other *termname* entries that has this capability gives a different value for that capability.

The order of the other *termname* entries is significant. Since the `terminfo` compiler `tic` does a left-to-right scan of the capabilities, specifying two `use=` entries that contain differing entries for the same capabilities will produce different results,

## infocmp(1M)

depending on the order in which the entries are given. `infocmp` will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a `use=` entry that contains, it will cause the second specification to be ignored. Using `infocmp` to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying superfluous `use=` fields. `infocmp` will flag any superfluous `use=` fields.

`-s` Sorts the fields within each type according to the argument below:

- `d` Leave fields in the order that they are stored in the `terminfo` database.
- `i` Sort by `terminfo` name.
- `l` Sort by the long C variable name.
- `c` Sort by the `termcap` name.

If the `-s` option is not given, the fields are sorted alphabetically by the `terminfo` name within each type, except in the case of the `-C` or the `-L` options, which cause the sorting to be done by the `termcap` name or the long C variable name, respectively.

`-v` Print out tracing information on standard error as the program runs.

`-V` Print out the version of the program in use on standard error and exit.

`-l` Print the fields one to a line. Otherwise, the fields are printed several to a line to a maximum width of 60 characters.

`-width` Changes the output to *width* characters.

The location of the compiled `terminfo` database is taken from the environment variable `TERMINFO`. If the variable is not defined, or the terminal is not found in that location, the system `terminfo` database, usually in `/usr/share/lib/terminfo`, is used. The options `-A` and `-B` may be used to override this location.

`-A directory` Set `TERMINFO` for the first *termname*.

`-B directory` Set `TERMINFO` for the other *termnames*. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing descriptions for the same terminal created by different people.

**FILES** `/usr/share/lib/terminfo/?/*` Compiled terminal description database.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

infocmp(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | in.ftpd, ftpd – file transfer protocol server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>in.ftpd</b> [-d1] [-t <i>timeout</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | in.ftpd is the Internet File Transfer Protocol (FTP) server process. The server is invoked by the Internet daemon inetd(1M) each time a connection to the FTP service (see services(4)) is made.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>-d                    Debugging information is logged to the system log daemon syslogd(1M).</p> <p>-1                    Each FTP session is logged to the system log daemon syslogd(1M).</p> <p>-t <i>timeout</i>        Set the inactivity timeout period to <i>timeout</i> seconds. The FTP server will timeout an inactive session after 15 minutes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Requests</b>    | <p>The FTP server currently supports the following FTP requests; case is not distinguished.</p> <p>ABOR        abort previous command</p> <p>ACCT        specify account (ignored)</p> <p>ALLO        allocate storage (vacuously)</p> <p>APPE        append to a file</p> <p>CDUP        change to parent of current working directory</p> <p>CWD        change working directory</p> <p>DELE        delete a file</p> <p>HELP        give help information</p> <p>LIST        give list files in a directory (ls -lg)</p> <p>MKD        make a directory</p> <p>MODE        specify data transfer <i>mode</i></p> <p>NLST        give name list of files in directory (ls)</p> <p>NOOP        do nothing</p> <p>PASS        specify password</p> <p>PASV        prepare for server-to-server transfer</p> <p>EPSV        extended passive command request</p> <p>LPSV        long passive command request</p> <p>PORT        specify data connection port</p> <p>EPRT        specify extended address for the transport connection</p> <p>LPRT        specify “long” address for the transport connection</p> |

|      |                                               |
|------|-----------------------------------------------|
| PWD  | print the current working directory           |
| QUIT | terminate session                             |
| RETR | retrieve a file                               |
| RMD  | remove a directory                            |
| RNFR | specify rename-from file name                 |
| RNTO | specify rename-to file name                   |
| STOR | store a file                                  |
| STOU | store a file with a unique name               |
| STRU | specify data transfer <i>structure</i>        |
| TYPE | specify data transfer <i>type</i>             |
| USER | specify user name                             |
| XCUP | change to parent of current working directory |
| XCWD | change working directory                      |
| XMKD | make a directory                              |
| XPWD | print the current working directory           |
| XRMD | remove a directory                            |

The remaining FTP requests specified in *RFC 959* are recognized, but not implemented.

The FTP server will abort an active file transfer only when the ABOR command is preceded by a Telnet "Interrupt Process" (IP) signal and a Telnet "Synch" signal in the command Telnet stream, as described in *RFC 959*. `in.ftpd` interprets file names according to the "globbing" conventions used by `sh(1)`. This allows users to utilize the metacharacters: `* ? [ ] { } ~`. `in.ftpd`'s `umask` (which it uses to create files during PUT operations) may be adjusted by adding the line

```
UMASK=nnn
```

to `/etc/default/ftpd`.

The banner returned by `in.ftpd` in the parenthetical portion of its greeting is configurable. The default is equivalent to `"uname -sr"` and will be used if no banner is set in `/etc/default/ftpd`. To set the banner, add a line of the form

```
BANNER="..."
```

to `/etc/default/ftpd`. Nonempty banner strings are fed to shells for evaluation.

The default banner may also be obtained by

## in.ftpd(1M)

```
BANNER="'uname -s' 'uname -r'"
and no banner will be printed if /etc/default/ftpd contains
```

```
BANNER="
```

`in.ftpd` authenticates users according to four rules.

First, the user name must be in the password data base, `/etc/passwd`, and have a password that is not NULL. A password must always be provided by the client before any file operations may be performed. The PAM framework (see `SECURITY` below) is used to verify that the correct password was entered.

Second, if the user name appears in the file `/etc/ftpusers`, ftp access is denied. The default list of users in `/etc/ftpusers` includes all of the accounts in `passwd(4)`. See `ftpusers(4)`.

Third, ftp access is denied if the user's shell is not a shell listed in `getusershell(3C)`.

Fourth, if the user name is "anonymous" or "ftp", an entry for the user name ftp must be present in the password and shadow files. The user is then allowed to log in by specifying any password — by convention this is given as the user's e-mail address (such as `user@host.Sun.COM`). Do not specify a valid shell in the password entry of the ftp user, and do not give it a valid password (use NP in the encrypted password field of the shadow file).

For anonymous ftp users, `in.ftpd` takes special measures to restrict the client's access privileges. The server performs a `chroot(2)` command to the home directory of the "ftp" user. In order that system security is not breached, it is recommended that the "ftp" subtree be constructed with care; the following rules are suggested.

```
~ftp
```

Make the home directory owned by `root` and unwritable by anyone.

```
~ftp/bin
```

Make this directory owned by the superuser and unwritable by anyone. Make this a symbolic link to `~ftp/usr/bin`. The program `ls(1)` must be present to support the list commands. This program should have mode 111.

```
~ftp/usr/lib
```

Make this directory owned by the superuser and unwritable by anyone. Copy the following shared libraries from `/usr/lib` into this directory:

```
ld.so.1*
libc.so.1*
libdl.so.1*
libmp.so.2*
libnsl.so.1*
libsocket.so.1*
nss_compat.so.1*
```

```
nss_dns.so.1*
nss_files.so.1*
nss_nis.so.1*
nss_nisplus.so.1*
nss_xfn.so.1*
straddr.so*
straddr.so.2*
```

~ftp/etc

Make this directory owned by the superuser and unwritable by anyone. Copies of the files `passwd(4)`, `group(4)`, and `netconfig(4)` must be present for the `ls(1)` command to work properly. These files should be mode 444.

~ftp/pub

Make this directory mode 755 and owned by root. Users should then place files which are to be accessible via the anonymous account in this directory.

~ftp/dev

Make this directory owned by the superuser and unwritable by anyone. First perform `ls -lL` on the device files listed below to determine their major and minor numbers, then use `mknod` to create them in this directory.

```
/dev/zero
/dev/tcp
/dev/udp
/dev/ticotsord
```

Set the read and write mode on these nodes to 666 so that passive ftp will not fail with “permission denied” errors.

~ftp/usr/share/lib/zoneinfo

Make this directory mode 555 and owned by the superuser. Copy its contents from `/usr/share/lib/zoneinfo`. This enables `ls -l` to display time and date stamps correctly.

## SECURITY

`in.ftpd` uses `pam(3PAM)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the module to be used for `in.ftpd`. Here is a partial `pam.conf` file with entries for the `in.ftpd` command using the UNIX authentication, account management, and session management module.

|     |         |          |                                 |
|-----|---------|----------|---------------------------------|
| ftp | auth    | required | /usr/lib/security/pam_unix.so.1 |
| ftp | account | required | /usr/lib/security/pam_unix.so.1 |
| ftp | session | required | /usr/lib/security/pam_unix.so.1 |

## in.ftpd(1M)

If there are no entries for the `ftp` service, then the entries for the "other" service will be used. Unlike `login`, `passwd`, and other commands, the `ftp` protocol will only support a single password. Using multiple modules will prevent `in.ftpd` from working properly.

**USAGE** The `in.ftpd` command is IPv6-enabled. See `ip6(7P)`.

### EXAMPLES **EXAMPLE 1** Setting Up An Anonymous Ftp

To set up anonymous ftp, add the following entry to the `/etc/passwd` file. In this example, `/export/ftp` was chosen to be the anonymous ftp area, and the shell is the non-existent file `/nosuchshell`. This prevents users from logging in as the ftp user.

```
ftp:x:30000:30000:Anonymous FTP:/export/ftp:/nosuchshell
```

Add the following entry to the `/etc/shadow` file:

```
ftp:NP:6445:.....:
```

The following shell script sets up the anonymous ftp area. It presumes that names are resolved using NIS.

```
#!/bin/sh
script to setup anonymous ftp area
#

verify you are root
/usr/bin/id | grep -w 'uid=0' >/dev/null 2>&1
if ["$?" != "0"]; then
 echo
 exit 1
fi

handle the optional command line argument
case $# in

 # the default location for the anon ftp comes from the passwd file
 0) ftphome=`getent passwd ftp | cut -d: -f6`
 ;;

 1) if ["$1" = "start"]; then
 ftphome=`getent passwd ftp | cut -d: -f6`
 else
 ftphome=$1
 fi
 ;;

 *) echo "Usage: $0 [anon-ftp-root]"
 exit 1
 ;;

esac

if [-z "${ftphome}"]; then
 echo "$0: ftphome must be non-null"
 exit 2
fi
```

**EXAMPLE 1** Setting Up An Anonymous Ftp (Continued)

```

case ${ftphome} in
 /*) # ok
 ;;

 *) echo "$0: ftphome must be an absolute pathname"
 exit 1
 ;;
esac

This script assumes that ftphome is neither / nor /usr so ...
if [-z "${ftphome}" -o "${ftphome}" = "/" -o "${ftphome}" = "/usr"]; then
 echo "$0: ftphome must be non-null and neither / or /usr"
 exit 2
fi

If ftphome does not exist but parent does, create ftphome
if [! -d ${ftphome}]; then
 # lack of -p below is intentional
 mkdir ${ftphome}
fi
chown root ${ftphome}
chmod 555 ${ftphome}

echo Setting up anonymous ftp area ${ftphome}

Ensure that the /usr directory exists
if [! -d ${ftphome}/usr]; then
 mkdir -p ${ftphome}/usr
fi
Now set the ownership and modes to match the man page
chown root ${ftphome}/usr
chmod 555 ${ftphome}/usr

Ensure that the /usr/bin directory exists
if [! -d ${ftphome}/usr/bin]; then
 mkdir -p ${ftphome}/usr/bin
fi
Now set the ownership and modes to match the man page
chown root ${ftphome}/usr/bin
chmod 555 ${ftphome}/usr/bin

this may not be the right thing to do
but we need the bin -> usr/bin link
rm -f ${ftphome}/bin
ln -s usr/bin ${ftphome}/bin

Ensure that the /usr/lib and /etc directories exist
if [! -d ${ftphome}/usr/lib]; then
 mkdir -p ${ftphome}/usr/lib
fi
chown root ${ftphome}/usr/lib
chmod 555 ${ftphome}/usr/lib

```

**EXAMPLE 1** Setting Up An Anonymous Ftp (Continued)

```

if [! -d ${ftphome}/usr/lib/security]; then
 mkdir -p ${ftphome}/usr/lib/security
fi
chown root ${ftphome}/usr/lib/security
chmod 555 ${ftphome}/usr/lib/security

if [! -d ${ftphome}/etc]; then
 mkdir -p ${ftphome}/etc
fi
chown root ${ftphome}/etc
chmod 555 ${ftphome}/etc

a list of all the commands that should be copied to ${ftphome}/usr/bin
/usr/bin/ls is needed at a minimum.
ftpcmd="
 /usr/bin/ls
"

${ftphome}/usr/lib needs to have all the libraries needed by the above
commands, plus the runtime linker, and some name service libraries

to resolve names. We just take all of them here.

ftplib=`ldd $ftpcmd | nawk ' $3 ~ /lib/ { print $3 }' | sort | uniq`
ftplib="$ftplib /usr/lib/nss_* /usr/lib/straddr* /usr/lib/libmp.so*"
ftplib="$ftplib /usr/lib/libnsl.so.1 /usr/lib/libsocket.so.1 /usr/lib/ld.so.1"
ftplib=`echo $ftplib | tr ' ' '\n' | sort | uniq`

cp $ftplib ${ftphome}/usr/lib
chmod 555 ${ftphome}/usr/lib/*

cp /usr/lib/security/* ${ftphome}/usr/lib/security
chmod 555 ${ftphome}/usr/lib/security/*

cp $ftpcmd ${ftphome}/usr/bin
chmod 111 ${ftphome}/usr/bin/*

you also might want to have separate minimal versions of passwd and group
cp /etc/passwd /etc/group /etc/netconfig /etc/pam.conf ${ftphome}/etc
chmod 444 ${ftphome}/etc/*

need /etc/default/init for timezone to be correct
if [! -d ${ftphome}/etc/default]; then
 mkdir ${ftphome}/etc/default
fi
chown root ${ftphome}/etc/default
chmod 555 ${ftphome}/etc/default
cp /etc/default/init ${ftphome}/etc/default
chmod 444 ${ftphome}/etc/default/init

Copy timezone database
mkdir -p ${ftphome}/usr/share/lib/zoneinfo
(cd ${ftphome}/usr/share/lib/zoneinfo

```

**EXAMPLE 1** Setting Up An Anonymous Ftp (Continued)

```

(cd /usr/share/lib/zoneinfo; find . -print |
cpio -o) 2>/dev/null | cpio -imdu 2>/dev/null
find . -print | xargs chmod 555
find . -print | xargs chown root
)

Ensure that the /dev directory exists
if [! -d ${ftphome}/dev]; then
 mkdir -p ${ftphome}/dev
fi

make device nodes. ticotsord and udp are necessary for
'ls' to resolve NIS names.

for device in zero tcp udp ticotsord ticlts
do
 line=`ls -lL /dev/${device} | sed -e 's/,//'`
 major=`echo $line | awk '{print $5}'`
 minor=`echo $line | awk '{print $6}'`
 rm -f ${ftphome}/dev/${device}
 mknod ${ftphome}/dev/${device} c ${major} ${minor}
done

chmod 666 ${ftphome}/dev/*

Now set the ownership and modes
chown root ${ftphome}/dev
chmod 555 ${ftphome}/dev

uncomment the below if you want a place for people to store things,
but beware the security implications
#if [! -d ${ftphome}/pub]; then
mkdir -p ${ftphome}/pub
#fi
#chown root ${ftphome}/pub
#chmod 1755 ${ftphome}/pub

```

After running this script, edit the files in `~ftp/etc` to make sure all non-public information is removed.

**ATTRIBUTES** See attributes (5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**FILES** `/etc/default/ftpd`  
`/etc/ftpusers` file listing users for whom ftp login privileges are disallowed.

**DIAGNOSTICS** in.ftpd logs various errors to syslogd, with a facility code of daemon.

**Info Severity** These messages are logged only if the -l flag is specified.

FTPD: connection from *host* at time  
A connection was made to ftpd from the host *host* at the date and time *time*.

FTPD: User *user* timed out after *timeout* seconds at time  
The user *user* was logged out because they had not entered any commands after *timeout* seconds; the logout occurred at the date and time *time*.

**Debug Severity** These messages are logged only if the -d flag is specified.

FTPD: command: *command*  
A command line containing *command* was read from the FTP client.

lost connection  
The FTP client dropped the connection.

<— *replycode*  
<— *replycode*—  
A reply was sent to the FTP client with the reply code *replycode*. The next message logged will include the message associated with the reply. If a - follows the reply code, the reply is continued on later lines.

**NOTES** The anonymous ftp account is inherently dangerous and should be avoided when possible.

The name service caching daemon `/usr/sbin/nscd` may interfere with some of the functionality of anonymous ftp. The *sublogin* feature does not work unless caching for passwd is disabled in `/etc/nscd.conf`.

The server must run as the superuser to create sockets with privileged port numbers. It maintains an effective user id of the logged in user, reverting to the superuser only when binding addresses to sockets. The possible security holes have been extensively scrutinized, but are possibly incomplete.

in.ftpd(1M)

The file `/etc/ftpusers`, which is now included as part of Solaris, contains a list of users who cannot access the system; the default list of users in `/etc/ftpusers` includes all of the accounts in `passwd(4)`. See `ftpusers(4)`.

## init(1M)

| <b>DESCRIPTION</b>             | init is a general process spawner. Its primary role is to create processes from information stored in the file <code>/etc/inittab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |        |                                                                                                         |                |                                                                                                           |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |                                                                                                                                                                                                     |
| <b>Run Level Defined</b>       | At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by <code>init</code> for each of these run levels are defined in <code>/etc/inittab</code> . <code>init</code> can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs <code>/sbin/init</code> . This sends appropriate signals to the original <code>init</code> spawned by the operating system at boot time, saying which run level to invoke.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |        |                                                                                                         |                |                                                                                                           |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |                                                                                                                                                                                                     |
| <b>init and System Booting</b> | <p>When the system is booted, <code>init</code> is invoked and the following occurs. First, it reads <code>/etc/default/init</code> to set environment variables. This is typically where TZ (time zone) and locale-related environments such as LANG or LC_CTYPE get set.</p> <p><code>init</code> then looks in <code>/etc/inittab</code> for the <code>initdefault</code> entry (see <code>inittab(4)</code>). If the <code>initdefault</code> entry:</p> <table><tr><td>exists</td><td><code>init</code> usually uses the run level specified in that entry as the initial run level to enter.</td></tr><tr><td>does not exist</td><td><code>/etc/inittab</code>, <code>init</code> asks the user to enter a run level from the system console.</td></tr><tr><td>S or s</td><td><code>init</code> goes to the single-user state. In this state, the system console device (<code>/dev/console</code>) is opened for reading and writing and the command <code>/sbin/su</code>, (see <code>su(1M)</code>), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.</td></tr><tr><td>0–6</td><td><code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.</td></tr></table> <p>If this is the first time since power up that <code>init</code> has entered a run level other than single-user state, <code>init</code> first scans <code>/etc/inittab</code> for <code>boot</code> and <code>bootwait</code> entries (see <code>inittab(4)</code>). These entries are performed before any other processing of <code>/etc/inittab</code> takes place, providing that the run level entered matches that of the</p> | exists | <code>init</code> usually uses the run level specified in that entry as the initial run level to enter. | does not exist | <code>/etc/inittab</code> , <code>init</code> asks the user to enter a run level from the system console. | S or s | <code>init</code> goes to the single-user state. | S or s                         | <code>init</code> goes to the single-user state. In this state, the system console device ( <code>/dev/console</code> ) is opened for reading and writing and the command <code>/sbin/su</code> , (see <code>su(1M)</code> ), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), <code>init</code> only re-initializes to the single-user state if <code>/etc/inittab</code> does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |        |                                                                                                         |                |                                                                                                           |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |                                                                                                                                                                                                     |
| 0–6                            | <code>init</code> enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |        |                                                                                                         |                |                                                                                                           |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |                                                                                                                                                                                                     |

entry. In this way any special initialization of the operating system, such as mounting file systems, can take place before users are allowed onto the system. `init` then scans `/etc/inittab` and executes all other entries that are to be processed for that run level.

To spawn each process in `/etc/inittab`, `init` reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by `/etc/inittab`, `init` waits for one of its descendant processes to die, a powerfail signal, or a signal from another `init` or `telinit` process to change the system's run level. When one of these conditions occurs, `init` re-examines `/etc/inittab`.

**inittab Additions**

New entries can be added to `/etc/inittab` at any time; however, `init` still waits for one of the above three conditions to occur before re-examining `/etc/inittab`. To get around this, `init Q` or `init q` command wakes `init` to re-examine `/etc/inittab` immediately.

When `init` comes up at boot time and whenever the system changes from the single-user state to another run state, `init` sets the `ioctl(2)` states of the console to those modes saved in the file `/etc/ioctl.syscon`. `init` writes this file whenever the single-user state is entered.

**Run Level Changes**

When a run level change request is made, `init` sends the warning signal (`SIGTERM`) to all processes that are undefined in the target run level. `init` waits five seconds before forcibly terminating these processes by sending a kill signal (`SIGKILL`).

When `init` receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in `/var/adm/utmpx` and `/var/adm/wtmpx` if it exists (see `who(1)`). A history of the processes spawned is kept in `/var/adm/wtmpx`.

If `init` receives a powerfail signal (`SIGPWR`) it scans `/etc/inittab` for special entries of the type `powerfail` and `powerwait`. These entries are invoked (if the run levels permit) before any further processing takes place. In this way `init` can perform various cleanup and recording functions during the powerdown of the operating system.

**/etc/defaults/init File**

Default values can be set for the following flags in `/etc/default/init`. For example: `TZ=US/Pacific`

|                          |                                                                                                                                                           |

|                 | <code>LC_TIME</code> | Time formatting information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                 | <code>LC_ALL</code>  | If set, all other <code>LC_*</code> environmental variables take-on this value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                 | <code>LANG</code>    | If <code>LC_ALL</code> is not set, and any particular <code>LC_*</code> is also not set, the value of <code>LANG</code> is used for that particular environmental variable.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>telinit</b>  |                      | <code>telinit</code> , which is linked to <code>/sbin/init</code> , is used to direct the actions of <code>init</code> . It takes a one-character argument and signals <code>init</code> to take the appropriate action.                                                                                                                                                                                                                                                                                                                                |
| <b>SECURITY</b> |                      | <code>init</code> uses <code>pam(3PAM)</code> for session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code> , specifies the session management module to be used for <code>init</code> . Here is a partial <code>pam.conf</code> file with entries for <code>init</code> using the UNIX session management module.<br><br><code>init session required /usr/lib/security/pam_unix.so.1</code><br><br>If there are no entries for the <code>init</code> service, then the entries for the "other" service will be used. |
| <b>OPTIONS</b>  | <code>0</code>       | Go into firmware.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                 | <code>1</code>       | Put the system in system administrator mode. All local file systems are mounted. Only a small set of essential kernel processes are left running. This mode is for administrative tasks such as installing optional utility packages. All files are accessible and no users are logged in on the system.                                                                                                                                                                                                                                                |
|                 | <code>2</code>       | Put the system in multi-user mode. All multi-user environment terminal processes and daemons are spawned. This state is commonly referred to as the multi-user state.                                                                                                                                                                                                                                                                                                                                                                                   |
|                 | <code>3</code>       | Extend multi-user mode by making local resources available over the network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                 | <code>4</code>       | Is available to be defined as an alternative multi-user environment configuration. It is not necessary for system operation and is usually not used.                                                                                                                                                                                                                                                                                                                                                                                                    |
|                 | <code>5</code>       | Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                 | <code>6</code>       | Stop the operating system and reboot to the state defined by the <code>initdefault</code> entry in <code>/etc/inittab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                 | <code>a, b, c</code> | process only those <code>/etc/inittab</code> entries having the <code>a, b, or c</code> run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.                                                                                                                                                                                                                                                                                                                   |
|                 | <code>Q, q</code>    | Re-examine <code>/etc/inittab</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                 | <code>S, s</code>    | Enter single-user mode. This is the only run level that doesn't require the existence of a properly formatted <code>/etc/inittab</code> file.                                                                                                                                                                                                                                                                                                                                                                                                           |

If this file does not exist, then by default, the only legal run level that `init` can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by `init` or `init.d` scripts that should only be running in multi-user mode are killed. In addition, any process that has a `utmpx` entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including `ttymon` login services, are killed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `login(1)`, `sh(1)`, `stty(1)`, `who(1)`, `shutdown(1M)`, `su(1M)`, `ttymon(1M)`, `ioctl(2)`, `kill(2)`, `ctime(3C)`, `pam(3PAM)`, `inittab(4)`, `pam.conf(4)`, `utmpx(4)`, `attributes(5)`, `pam_unix(5)`, `termio(7I)`

**DIAGNOSTICS** If `init` finds that it is respawning an entry from `/etc/inittab` more than ten times in two minutes, assumes that there is an error in the command string in the entry, and generates an error message on the system console. It will then refuse to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned `init` or `telinit`. This prevents `init` from eating up system resources when someone makes a typographical error in the `inittab` file, or a program is removed that is referenced in `/etc/inittab`.

**NOTES** `init` and `telinit` can be run only by a privileged user.

The `S` or `s` state must not be used indiscriminately in `/etc/inittab`. When modifying this file, it is best to avoid adding this state to any line other than `initdefault`.

## init(1M)

If a default state is not specified in the `initdefault` entry in `/etc/inittab`, state `6` is entered. Consequently, the system will loop by going to firmware and rebooting continuously.

If the `utmpx` file cannot be created when booting the system, the system will boot to state `"s"` regardless of the state specified in the `initdefault` entry in `/etc/inittab`. This can occur if the `/var` file system is not accessible.

| <b>SYNOPSIS</b>           | <code>/etc/init.d/init.wbem start   stop   status</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b>        | <p>The <code>init.wbem</code> utility is run automatically during installation and each time the system is rebooted. This utility manipulates the CIM Object Manager (CIMOM) and the Solaris Management Console server, both of which run combined in a single process. <code>init.wbem</code> can be used to start, stop, or retrieve status from the server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>CIM Object Manager</b> | <p>The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.</p> <p>When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data.</p> <p>When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.</p> <p>At startup, the CIM Object Manager performs the following functions:</p> <ul style="list-style-type: none"> <li>■ Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 80.</li> <li>■ Sets up a connection to the CIM Object Manager Repository.</li> <li>■ Waits for incoming requests.</li> </ul> <p>During normal operations, the CIM Object Manager performs the following functions:</p> <ul style="list-style-type: none"> <li>■ Performs security checks to authenticate user login and authorization to access namespaces.</li> <li>■ Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.</li> <li>■ Routes requests to the appropriate provider or to the CIM Object Manager Repository.</li> <li>■ Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.</li> </ul> <p>A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to a CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.</p> |

init.wbem(1M)

**Solaris Management Console Server**

The Solaris Management Console server is the back end to the front end console, `smc(1M)`. It provides tools for the console to download and performs common services for the console and its tools to use, such as authentication, authorization, logging, messaging, and persistence.

**System Booting**

The `init.wbem` script is installed in the `/etc/init.d` directory. A link to it exists in `/etc/rc2.d/S90wbem`, which is run with the `start` option when init state 2 is entered (normally at boot time). Other links to it exist in `/etc/rc0.d/K36wbem`, `/etc/rc1.d/K36wbem`, and `/etc/rcS.d/K36wbem`, which are run with the `stop` option when init states 0, 1, and S are entered (normally at system halt, or when entering "system administrator mode" or single user mode).

**OPTIONS**

The following options are supported:

- `start` Starts the CIMOM and Solaris Management Console server on the local host.
- `stop` Stops the CIMOM and Solaris Management Console server on the local host.
- `status` Gets the status of the CIMOM and Solaris Management Console server on the local host.

**NOTES**

When the `init.wbem` script is run, it does not run the CIMOM and Solaris Management Console server directly. The server process is in Java and is too heavyweight to be run immediately at system boot time. Instead, a lightweight process is run which listens on the ports the CIMOM and the Solaris Management Console server normally use, running the two servers the first time it gets a connection on either port, thus acting similarly to `inetd(1M)`.

Because Java programs cannot inherit file descriptors as other programs can, there is a small time period from when the first connection is made until the server is fully operational where client connections may be dropped. WBEM clients are immune to this, as they will retry until the server come online. Solaris Management Console clients are not immune, and it may be necessary to manually reconnect, though this should not happen in the common case.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server: starting queue processing, transferring print jobs, retrieving terse status, retrieving verbose status, and canceling print jobs.</p> <p>in.lpd is started from inetd (see inetd(1M)). inetd waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.</p> |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                      Successful completion.</p> <p>non-zero              An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |

| <b>NAME</b>        | in.mpathd – daemon for network adapter (NIC) failure detection, recovery, automatic failover and failback                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <code>/sbin/in.mpathd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>in.mpathd</code> daemon performs Network Interface Card (NIC) failure and repair detection. In the event of a NIC failure, it causes IP network access from the failed NIC to failover to a standby NIC, if available, or to any another operational NIC that has been configured as part of the same network multipathing group. Once the failed NIC is repaired, all network access will be restored to the repaired NIC.</p> <p>The <code>in.mpathd</code> daemon detects NIC failure and repair by sending and receiving ICMP echo requests and replies on each NIC. The <code>in.mpathd</code> daemon sends the probes to on-link routers. If no routers are available, it sends the probes to neighboring hosts. Thus, for network failure detection and repair, there must be at least one neighbor on each link that responds to ICMP echo request probes.</p> <p><code>in.mpathd</code> needs a special test address on each NIC for the purpose of sending and receiving probes on each NIC. Use the <code>ifconfig</code> command <code>-failover</code> option to configure these test addresses. See <code>ifconfig(1M)</code>. The test address must belong to a subnet that is known to the hosts and routers on the link.</p> <p><code>in.mpathd</code> works on both IPv4 and IPv6. If IPv4 is plumbed on a NIC, an IPv4 test address is configured on the NIC, and the NIC is configured as part of a network multipathing group, then <code>in.mpathd</code> will start sending ICMP probes on the NIC using IPv4.</p> <p>In the case of IPv6, the link-local address must be configured as the test address. The <code>in.mpathd</code> daemon will not accept a non-link-local address as a test address. If the NIC is part of a multipathing group, and the test address has been configured, then <code>in.mpathd</code> will probe the NIC for failures using IPv6.</p> <p>Even if both the IPv4 and IPv6 protocol streams are plumbed, it is sufficient to configure only one of the two, that is, either an IPv4 test address or an IPv6 test address on a NIC. If only an IPv4 test address is configured, it probes using only ICMPv4. If only an IPv6 test address is configured, it probes using only ICMPv6. If both type test addresses are configured, it probes using both ICMPv4 and ICMPv6.</p> <p>The <code>in.mpathd</code> daemon accesses three variable values in <code>/etc/default/mpathd</code>: <code>FAILURE_DETECTION_TIME</code>, <code>FAILBACK</code> and <code>TRACK_INTERFACES_ONLY_WITH_GROUPS</code>.</p> <p>The <code>FAILURE_DETECTION_TIME</code> variable specifies the NIC failure detection time. The shorter the failure detection time, the greater the volume of probe traffic. The default value of <code>FAILURE_DETECTION_TIME</code> is 10 seconds. This means that NIC failure will be detected by <code>in.mpathd</code> within 10 seconds. The NIC repair detection time cannot be configured; however, it is defined as double the value of <code>FAILURE_DETECTION_TIME</code>.</p> |

in.mpathd(1M)

By default, `in.mpathd` does failure detection only on NICs that are configured as part of a multipathing group. You can set `TRACK_INTERFACES_ONLY_WITH_GROUPS` to `no` to enable failure detection by `in.mpathd` on all NICs, even if they are not part of a multipathing group. However, `in.mpathd` cannot do failover from a failed NIC if it is not part of a multipathing group.

The `in.mpathd` daemon will restore network traffic back to the previously failed NIC, after it has detected a NIC repair. To disable this, set the value of `FAILBACK` to `no` in `/etc/default/mpathd`.

**FILES** `/etc/default/mpathd` Contains default values used by the `in.mpathd` daemon.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

**SEE ALSO** `ifconfig(1M)`, `attributes(5)`, `icmp(7P)`, `icmp6(7P)`,

*System Administration Guide, Volume 3*

**DIAGNOSTICS** IFF\_NOFAILOVER address

*address* is not unique and failure detection is not possible

Every test address that is configured must be unique on the system. Otherwise `in.mpathd` cannot do failure detection. Since the IPv6 test address is a link-local address, which in turn is derived from the ethernet address, each NIC must have a unique MAC address.

NIC *interface\_name* of group *group\_name* is not plumbed for IPv[4|6] and may affect failover capability

All NICs in a multipathing group must be homogeneously plumbed. For example, if a NIC is plumbed for IPv4, then all NICs in the group must be plumbed for IPv4. The streams modules pushed on all NICs must be identical.

Failures cannot be detected on *interface\_name* as no IFF\_NOFAILOVER address is available

Every NIC that is configured as part of a multipathing group must have a test address, which can be either IPv4 or IPv6, or both. Otherwise `in.mpathd` cannot probe the NIC, and this message is displayed.

Invalid failure detection *time* assuming default 10000

An invalid value was encountered for `FAILURE_DETECTION_TIME` in the `/etc/default/mpathd` file.

Too small failure detection time of *time* assuming minimum 100

## in.mpathd(1M)

The minimum value that can be specified for *FAILURE\_DETECTION\_TIME* is currently 100 milliseconds.

Invalid value for *FAILBACK* *value*

Valid values for the boolean variable *FAILBACK* are *yes* or *no*.

Invalid value for *TRACK\_INTERFACES\_ONLY\_WITH\_GROUPS* *value*

Valid values for the boolean variable

*TRACK\_INTERFACES\_ONLY\_WITH\_GROUPS* are *yes* or *no*.

Cannot meet requested failure detection time of

*time* ms on (inet[4 | 6] *interface\_name*)

new failure detection is *time* ms

The round trip time for ICMP probes is higher than the specified failure detection time. The network is probably congested or the probe targets are loaded.

*in.mpathd* automatically increases the failure detection time to whatever it can achieve under these conditions.

Improved failure detection time *time* ms

The round trip time for ICMP probes has now decreased and *in.mpathd* has lowered the failure detection time correspondingly.

NIC failure detected on *interface\_name*

*in.mpathd* has detected NIC failure on *interface\_name*, and has set the *IFF\_FAILED* flag on NIC *interface\_name*.

Successfully failed over from NIC *interface\_name1* to

NIC *interface\_name2*

*in.mpathd* has caused the network traffic to failover from NIC *interface\_name1* to NIC *interface\_name2*, which is part of the multipathing group.

NIC repair detected on *interface\_name*

*in.mpathd* has detected that NIC *interface\_name* is repaired and operational. If the *IFF\_FAILED* flag on the NIC was previously set, it will be reset..

Successfully failed back to NIC *interface\_name*

*in.mpathd* has restored network traffic back to NIC *interface\_name*, which is now repaired and operational.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | in.named, named – Internet domain name server (DNS)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>in.named</b> [-d <i>debuglevel</i> ] [-p <i>port#</i> ] [ [-b   -c] <i>config_file</i> ] [-fqr] [-u <i>user_name</i> ] [-g <i>group_name</i> ] [-t <i>directory</i> ] [-w <i>directory</i> ] [ <i>config_file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>in.named is the Internet domain name server. For more information on the Internet name-domain system, see <i>RFC 1033</i>, <i>RFC 1034</i> and <i>RFC 1035</i>.</p> <p>When run without any arguments, in.named reads the default configuration file <i>/etc/named.conf</i>, reads any initial data, and listens for queries. If you give a <i>config_file</i> argument at the end of the command line, it will override any <i>config_file</i> that you specified by using the -b or -c options.</p> <p>The <i>named.conf</i>(4) configuration file controls some of the options and behavior for in.named.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>in.named supports the following options:</p> <p>-b   c <i>configfile</i>                      Use an alternative configuration file. The default value for <i>configfile</i> is <i>/etc/named.conf</i>. The <i>configfile</i>, if any, specified at the end of the command line, overrides any value specified by this argument.</p> <p>-d <i>debuglevel</i>                          Print debugging information. The value of <i>debuglevel</i> determines the level of messages to print. If negative, <i>debuglevel</i> is set to 1.</p> <p>                                            The new debugging framework is considerably more sophisticated than in previous versions of in.named. The logging statement in the configuration file allows for multiple, distinct levels of debugging for each of a large set of categories of events, for example, for queries and transfers in and out. See <i>named.conf</i>(4).</p> <p>-f                                          Run this process in the foreground. The process will not fork(2). By default, in.named runs as a daemon in the background.</p> <p>-g <i>group_name</i>                          Specify the group the server should run as after it initializes. The value specified may be either a group name or a numeric group id.</p> <p>-p <i>port#</i>                                  Use the specified remote port number. in.named will send queries to this port number. By default, the value is the standard port number, that is, the port number returned by <i>getservbyname</i>(3SOCKET) for the service domain.</p> <p>                                            The in.named command previously supported the syntax:</p> <p>                                            -p <i>port#[/localport#]</i> where <i>port#</i> was the first port used</p> |

## in.named(1M)

when contacting remote servers and *localport#* was the service port bound by the local instance of *in.named*.

The current usage is equivalent to the old usage without *localport#* specified. This functionality can be specified with the *listen-on* clause options statement in the configuration file.

- q Trace all incoming queries. This option is deprecated in favor of the *queries* logging category of the logging statement in *named.conf*. See *named.conf*(4).
- r Turn recursion off in the server. Responses come only from local (primary or secondary) zones. You can use this option on root servers. By default, the server uses recursion. This option is deprecated and is overridden by the *recursion* clause of the *options* statement in the configuration file.
- t *directory* Specify the directory that the server is to *chroot*(2) into when it finishes processing command line arguments.
- u *user\_name* Specify the user that the server should run as after it initializes. The value of *user\_name* may be either a user name or a numeric user id. If the *-g* option is not invoked, then the group id will be the primary group of the user specified. Since *initgroups*(3C) is called, all of the user's group will be available to the server.
- v Report the version and exit.
- w *directory* Set the working directory of the server. The *directory* clause of the *options* statement overrides any value specified on the command line. The default working directory is the current directory (".").

For compatibility with older implementations any additional argument will be interpreted as the name of the configuration file. This argument overrides any *config\_file* specified by means of the *-b* or *-c* options. If no further argument is given, then the default configuration file, */etc/named.conf* is used.

### Master File Format

The master file consists of control information and a list of resources for objects in the zone. The file has the following form:

```
$INCLUDE <filename><opt_domain>
$ORIGIN <domain>
$TTL <ttd>
<domain><opt_ttl><opt_class><type><resource_record_data>
```

The fields are defined as follows:

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>domain</i>     | The value of <i>domain</i> can be "." for root, "@" for the current origin, or a standard domain name. If domain is a standard domain name that does not end with ".", the current origin is appended to the domain. Domain names ending with "." are not modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>opt_domain</i> | This field is used to define an origin for the data in an included file. It is equivalent to placing an \$ORIGIN statement before the first line of the included file. This field is optional. Neither the <i>opt_domain</i> field nor \$ORIGIN statements in the included file modify the current origin for this file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>tll</i>        | An integer number that sets the default time-to-live for future records that do not have an explicit <i>tll</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>opt_ttl</i>    | An optional integer number for the time-to-live field. If not set the <i>tll</i> is taken from the last \$TTL statement. If no \$TTL statement has occurred then the SOA minimum value is used, and a warning is generated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>opt_class</i>  | The object address type. Currently only one type is supported, IN, for objects connected to the DARPA Internet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>type</i>       | This field contains one of the following tokens. The data expected in the <i>resource_record_data</i> field is in parentheses: <ul style="list-style-type: none"> <li>A           A host address (dotted-quad IP address).</li> <li>NS           An authoritative name server (domain).</li> <li>MX           A mail exchanger (domain), preceded by a preference value (0..32767), with lower numeric values representing higher logical preferences.</li> <li>CNAME       The canonical name for an alias (domain).</li> <li>SOA          Marks the start of a zone of authority (domain of originating host, domain address of maintainer, a serial number and the following parameters in seconds: refresh, retry, expire and minimum <i>tll</i>). See RFC 883 and RFC 2308.</li> <li>NULL         A NULL resource record (no format or data).</li> <li>RP           A Responsible Person for some domain name (mailbox, TXT-referral).</li> </ul> |

|                          |                             |                                                                                                                                                                                                                                                                                                                                                                | The SOA specifies a serial number, which should be changed each time the master file is changed. Note that the serial number can be given as a dotted number, but this is a very unwise thing to do since the translation to normal integers is by means of concatenation rather than multiplication and addition. You can spell out the year, month, day of month, and 0.99 version number and still fit inside the unsigned 32-bit size of this field. (It's true that we will have to rethink this strategy in the year 4294, but we're not worried about it.)    |
|                          |                             |                                                                                                                                                                                                                                                                                                                                                                | Secondary servers check the serial number at intervals specified by the refresh time in seconds; if the serial number changes, a zone transfer will be done to load the new data. If a master server cannot be contacted when a refresh is due, the retry time specifies the interval at which refreshes should be attempted. If a master server cannot be contacted within the interval given by the expire time, all data from the zone is discarded by secondary servers. The minimum value is the cache time-to-live for negative answers. See <i>RFC 2308</i> . |

**NOTES** The boot file directives `domain` and `suffixes` are now obsolete. They have been replaced by a resolver-based implementation of suffixing for partially-qualified domain names. The earlier mechanisms failed under a number of situations, for example, when the local name server did not have complete information.

The following signals have the specified effect when sent to the server process using the `kill(1)` command:

## in.named(1M)

|          |                                                                                                                                                                 |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIGHUP   | Causes the server to read <code>named.conf</code> and reload the database. SIGHUP will also cause the server to check the serial number on all secondary zones. |
| SIGINT   | Dumps the current database and cache to <code>named_dump.db</code> .                                                                                            |
| SIGILL   | Dumps statistics data into <code>named.stats</code> . Statistics data is appended to the file.                                                                  |
| SIGTERM  | Saves any modified dynamic zones to the file system and shuts down the server.                                                                                  |
| SIGUSR1  | Turns on debugging. Each additional SIGUSR1 signal increments the debug level.                                                                                  |
| SIGUSR2  | Turns off debugging completely.                                                                                                                                 |
| SIGWINCH | Toggles logging of all incoming queries by means of <code>syslog(3C)</code> .                                                                                   |

| <b>NAME</b>        | in.ndpd – daemon for IPv6 autoconfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.ndpd [-adt] [-f <i>config_file</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>in.ndpd provides both the host and router autoconfiguration components of Neighbor Discovery for IPv6 and Stateless Address Autoconfiguration for IPv6. In particular, in.ndpd implements</p> <ul style="list-style-type: none"> <li>■ router discovery;</li> <li>■ prefix discovery;</li> <li>■ parameter discovery; and</li> <li>■ address autoconfiguration.</li> </ul> <p>Other aspects of Neighbor Discovery are implemented by ip6(7P), including:</p> <ul style="list-style-type: none"> <li>■ address resolution;</li> <li>■ neighbor unreachability detection; and</li> <li>■ redirect.</li> </ul> <p>The duplicate address detection function is implemented by ifconfig(1M).</p> <p>If the <code>/etc/inet/ndpd.conf</code> file does not exist or does not set the variable <code>AdvSendAdvertisements</code> to true for a network interface, then in.ndpd will make the node a host for that interface, that is, sending router solicitation messages and then using router advertisement messages it receives to autoconfigure the node. Note that in.ndpd only autoconfigures the addresses of global or site-local scope from the prefix advertisement.</p> <p>If <code>AdvSendAdvertisements</code> is set to true for an interface, then in.ndpd will perform router functions on that interface, that is, sending router advertisement messages to autoconfigure the attached hosts, but not use any advertisements it receives for autoconfiguration. However, when sending advertisements, in.ndpd will use the advertisements it sends itself to autoconfigure its prefixes. For improved robustness in.ndpd stores any autoconfigured IPv6 addresses and their expiration times in state files named <code>ndpd_state.interface</code> that are located in the <code>/var/inet</code> directory. Should in.ndpd fail to find any routers, it will use the state files as a fallback, autoconfiguring those addresses if the recorded addresses have remaining lifetime. This ensures that a host that reboots faster than the routers, for example after a short power failure, will continue using the addresses that it had before the power failure.</p> |
| <b>OPTIONS</b>     | <p>-a Turn off stateless address auto configuration. When set, the daemon does not autoconfigure any addresses and does not renumber any addresses.</p> <p>-d Turn on large amounts of debugging output on <code>stdout</code>. When set, the program runs in the foreground and stays attached to the controlling terminal.</p> <p>-f <i>config_file</i> Use <i>config_file</i> for configuration information instead of the default <code>/etc/inet/ndpd.conf</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## in.ndpd(1M)

-t Turn on tracing (printing) of all sent and received packets to stdout. When set, the program runs in the foreground and stays attached to the controlling terminal.

**FILES** /etc/inet/ndpd.conf Configuration file. Not needed on a host but required on a router to enable in.ndpd to advertise autoconfiguration information to the hosts.

/var/inet/ndpd\_state.interface Contains the addresses for interface. The existence of an address in this file does not imply that the address is usable, since the address lifetime may have expired.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** ifconfig(1M), ndpd.conf(4), attributes(5), icmp6(7p), ip6(7p) attributes(5)

Narten, T., Nordmark, E., Simpson, W., RFC 2461, *Neighbor Discovery for IP Version 6 (IPv6)*, The Internet Society, December 1998.

Thomson, S., Narten, T., RFC 2462, *IPv6 Stateless Address Autoconfiguration*, The Internet Society, December 1998.

**DIAGNOSTICS** Receipt of a SIGHUP signal will make in.ndpd restart and reread /etc/inet/ndpd.conf.

| <b>NAME</b>        | in.rarpd, rarpd – DARPA Reverse Address Resolution Protocol server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/in.rarpd [-d] -a /usr/sbin/in.rarpd [-d] device unit</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.</p> <p>RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the <code>ethers</code> and <code>hosts</code> databases, <code>in.rarpd</code> maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for <code>in.rarpd</code> to locate its IP address. <code>in.rarpd</code> issues no reply when it fails to locate an IP address.</p> <p><code>in.rarpd</code> uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.</li> <li>-d        Print assorted debugging messages while executing.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Starting An <code>in.rarpd</code> Daemon For Each Network Interface Name Returned From <code>/dev/ip</code>:</p> <p>The following command starts an <code>in.rarpd</code> for each network interface name returned from <code>/dev/ip</code>:</p> <pre>example# /usr/sbin/in.rarpd -a</pre> <p><b>EXAMPLE 2</b> Starting An <code>in.rarpd</code> Daemon On The Device <code>/dev/le</code> With The Device Instance Number 0</p> <p>The following command starts one <code>in.rarpd</code> on the device <code>/dev/le</code> with the device instance number 0.</p> <pre>example# /usr/sbin/in.rarpd le 0</pre>                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>                 | in.rdisc, rdisc – network router discovery daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>             | <pre> /usr/sbin/in.rdisc [-a] [-f] [-s] [send-address] [receive-address]  /usr/sbin/in.rdisc -r [-p preference] [-T interval] [send-address] [receive-address] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>          | <p>in.rdisc implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers. On a host, in.rdisc is invoked at boot time to populate the network routing tables with default routes. On a router, it is also invoked at boot time in order to start advertising the router to all the hosts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Host (First Form)</b>    | <p>On a host, in.rdisc listens on the ALL_HOSTS (224.0.0.1) multicast address for ROUTER_ADVERTISE messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.</p> <p>Optionally, in.rdisc can avoid waiting for routers to announce themselves by sending out a few ROUTER_SOLICITATION messages to the ALL_ROUTERS (224.0.0.2) multicast address when it is started.</p> <p>A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new <i>advertise</i> message is received from the router. The address will also be excluded from consideration if the host receives an <i>advertise</i> message with the preference being maximally negative.</p> |
| <b>Router (Second Form)</b> | <p>When in.rdisc is started on a router, it uses the SIOCGIFCONF ioctl(2) to find the interfaces configured into the system and it starts listening on the ALL_ROUTERS multicast address on all the interfaces that support multicast. It sends out <i>advertise</i> messages to the ALL_HOSTS multicast address advertising all its IP addresses. A few initial <i>advertise</i> messages are sent out during the first 30 seconds and after that it will transmit <i>advertise</i> messages approximately every 600 seconds.</p> <p>When in.rdisc receives a <i>solicitation</i> message, it sends an <i>advertise</i> message to the host that sent the <i>solicitation</i> message.</p> <p>When in.rdisc is terminated by a signal, it sends out an <i>advertise</i> message with the preference being maximally negative.</p>                                                                                                                                                                                                         |
| <b>OPTIONS</b>              | <p>-a           Accept all routers independent of the preference they have in their <i>advertise</i> messages. Normally, in.rdisc only accepts (and enters in the kernel routing tables) the router or routers with the highest preference.</p> <p>-f           Run in.rdisc forever even if no routers are found. Normally, in.rdisc gives up if it has not received any <i>advertise</i> message</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

in.rdisc(1M)

after soliciting three times, in which case it exits with a non-zero exit code. If `-f` is not specified in the first form then `-s` must be specified.

- `-r` Act as a router, rather than a host.
- `-s` Send three *solicitation* messages initially to quickly discover the routers when the system is booted. When `-s` is specified, `in.rdisc` exits with a non-zero exit code if it can not find any routers. This can be overridden with the `-f` option.
- `-p preference` Set the preference transmitted in the *solicitation* messages. The default is zero.
- `-T interval` Set the interval between transmitting the *advertise* messages. The default time is 600 seconds.

| <b>SYNOPSIS</b>    | <b>in.rexecd</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><i>in.rexecd</i> is the server for the <i>rexec(3SOCKET)</i> routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by <i>inetd(1M)</i>, and then executes the following protocol:</p> <ol style="list-style-type: none"> <li>1) The server reads characters from the socket up to a null (<code>\0</code>) byte. The resultant string is interpreted as an ASCII number, base 10.</li> <li>2) If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <code>stderr</code>. A second connection is then created to the specified port on the client's machine.</li> <li>3) A null terminated user name of at most 16 characters is retrieved on the initial socket.</li> <li>4) A null terminated password of at most 16 characters is retrieved on the initial socket.</li> <li>5) A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li> <li>6) <i>rexecd</i> then validates the user as is done at login time and, if the authentication was successful, changes to the user's home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.</li> <li>7) A null byte is returned on the connection associated with the <code>stderr</code> and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by <i>rexecd</i>.</li> </ol> |                |                 |              |         |
| <b>USAGE</b>       | <i>in.rexecd</i> and <i>rexecd</i> are IPv6-enabled. See <i>ip6(7P)</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>NAME</b>        | in.ripngd – network routing daemon for IPv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.ripngd [-s] [-q] [-t] [-p n] [-P] [-v ] [logfile]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>in.ripngd is the IPv6 equivalent of in.routed(1M). It is invoked at boot time to manage the network routing tables. The routing daemon uses the Routing Information Protocol for IPv6.</p> <p>In normal operation, in.ripngd listens on the udp(7P) socket port 521 for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.</p> <p>When in.ripngd is started, it uses the SIOCGLIFCONF ioctl(2) to find those directly connected IPv6 interfaces configured into the system and marked "up"; the software loopback interface is ignored. If multiple interfaces are present, it is assumed the host will forward packets between networks. in.ripngd then multicasts a request packet on each IPv6 interface and enters a loop, listening for request and response packets from other hosts.</p> <p>When a request packet is received, in.ripngd formulates a reply based on the information maintained in its internal tables. The response packet contains a list of known routes. With each route is a number specifying the number of bits in the prefix. The prefix is the number of bits in the high order part of an address that indicate the subnet or network that the route describes. Each route reported also has a "hop count" metric. A count of 16 or greater is considered "infinity." The metric associated with each route returned provides a metric relative to the sender.</p> <p>The request packets received by in.ripngd are used to update the routing tables if one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> <li>■ No routing table entry exists for the destination network or host, and the metric indicates the destination is "reachable, that is, the hop count is not infinite.</li> <li>■ The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.</li> <li>■ The existing entry in the routing table has not been updated for a period of time, defined to be 90 seconds, and the route is at least as cost-effective as the current route.</li> <li>■ The new route describes a shorter route to the destination than the one currently stored in the routing tables; this is determined by comparing the metric of the new route against the one stored in the table.</li> </ul> <p>When an update is applied, in.ripngd records the change in its internal tables and generates a response packet to all directly connected hosts and networks. To allow possible unstable situations to settle, in.ripngd waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables.</p> |

## in.ripngd(1M)

In addition to processing incoming packets, `in.ripngd` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

**OPTIONS** `in.ripngd` supports the following options:

- q Do not supply routing information.
- s Force `in.ripngd` to supply routing information whether it is acting as an internetwork router or not.
- p *n* Send and receive the routing packets from other routers using the UDP port number *n*.
- P Do not use poison reverse.
- t Print all packets sent or received to standard output. `in.ripngd` will not divorce itself from the controlling terminal. Accordingly, interrupts from the keyboard will kill the process.
- v Print all changes made to the routing tables to standard output with a timestamp.

Any other argument supplied is interpreted as the name of the file in which the actions of `in.ripngd`, as specified by this option or by `-t`, should be logged versus being sent to standard output.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `in.routed(1M)`, `ioctl(2)`, `attributes(5)`, `udp(7P)`

Malkin, G., Minnear, R., *RFC 2080, RIPng for IPv6*, January 1997.

**NOTES** The kernel's routing tables may not correspond to those of `in.ripngd` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

`in.ripngd` currently does not support all of the functionality of `in.routed(1M)`. Future releases may support more if appropriate.

`in.ripngd` initially obtains a routing table by examining the interfaces configured on a machine. It then sends a request on all directly connected networks for more routing

in.ripngd(1M)

information. `in.ripngd` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.ripngd` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by way of the `route(1M)` command. Therefore, these types of changes should not be done while `in.ripngd` is running. Rather, shut down `in.ripngd`, make the changes required, and then restart `in.ripngd`.

| <b>NAME</b>         | in.rlogind, rlogind – remote login server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                         |                                                     |                         |                                                     |                     |                   |                       |                                              |                     |                      |                       |                                              |
| <b>SYNOPSIS</b>     | <code>/usr/sbin/in.rlogind</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                         |                                                     |                         |                                                     |                     |                   |                       |                                              |                     |                      |                       |                                              |
| <b>DESCRIPTION</b>  | <p><code>in.rlogind</code> is the server for the <code>rlogin(1)</code> program. The server provides a remote login facility with authentication based on privileged port numbers.</p> <p><code>in.rlogind</code> is invoked by <code>inetd(1M)</code> when a remote login connection is established, and executes the following protocol:</p> <ul style="list-style-type: none"><li>■ The server checks the client's source port. If the port is not in the range 0-1023, the server aborts the connection.</li><li>■ The server checks the client's source address. If an entry for the client exists in both <code>/etc/hosts</code> and <code>/etc/hosts.equiv</code>, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in <code>/etc/hosts</code>, the user is prompted for a password, regardless of whether or not an entry for the client is present in <code>/etc/hosts.equiv</code>. See <code>hosts(4)</code> and <code>hosts.equiv(4)</code>.</li></ul> <p>Once the source port and address have been checked, <code>in.rlogind</code> allocates a pseudo-terminal and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the <code>stdin</code>, <code>stdout</code>, and <code>stderr</code> for a login process. The login process is an instance of the <code>login(1)</code> program, invoked with the <code>-r</code>.</p> <p>The login process then proceeds with the <code>pam(3PAM)</code> authentication process. See <b>SECURITY</b> below. If automatic authentication fails, it re-prompts the user to login.</p> <p>The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the <code>rlogin</code> program. In normal operation, a packet protocol is invoked to provide Ctrl-S and Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, <code>TERM</code>; see <code>environ(4)</code>.</p> |                         |                                                     |                         |                                                     |                     |                   |                       |                                              |                     |                      |                       |                                              |
| <b>USAGE</b>        | <code>rlogind</code> and <code>in.rlogind</code> are IPv6-enabled. See <code>ip6(7P)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                         |                                                     |                         |                                                     |                     |                   |                       |                                              |                     |                      |                       |                                              |
| <b>SECURITY</b>     | <p><code>in.rlogind</code> uses <code>pam(3PAM)</code> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>in.rlogind</code>. Here is a partial <code>pam.conf</code> file with entries for the <code>rlogin</code> command using the "rhosts" and UNIX authentication modules, and the UNIX account, session management, and password management modules.</p> <table><tr><td><code>rlogin</code></td><td><code>auth</code></td><td><code>sufficient</code></td><td><code>/usr/lib/security/pam_rhosts_auth.so.1</code></td></tr><tr><td><code>rlogin</code></td><td><code>auth</code></td><td><code>required</code></td><td><code>/usr/lib/security/pam_unix.so.1</code></td></tr><tr><td><code>rlogin</code></td><td><code>account</code></td><td><code>required</code></td><td><code>/usr/lib/security/pam_unix.so.1</code></td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <code>rlogin</code>     | <code>auth</code>                                   | <code>sufficient</code> | <code>/usr/lib/security/pam_rhosts_auth.so.1</code> | <code>rlogin</code> | <code>auth</code> | <code>required</code> | <code>/usr/lib/security/pam_unix.so.1</code> | <code>rlogin</code> | <code>account</code> | <code>required</code> | <code>/usr/lib/security/pam_unix.so.1</code> |

```
rlogin session required /usr/lib/security/pam_unix.so.1
```

With this configuration, the server checks the client's source address. If an entry for the client exists in both `/etc/hosts` and `/etc/hosts.equiv`, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in `/etc/hosts`, the user is prompted for a password, regardless of whether or not an entry for the client is present in `/etc/hosts.equiv`. See `hosts(4)` and `hosts.equiv(4)`.

If there are no entries for the `rlogin` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the "pam\_rhosts\_auth.so.1" entry will disable the `/etc/hosts.equiv` and `~/rhosts` authentication protocol and the user would always be forced to type the password. The *sufficient* flag indicates that authentication through the `pam_rhosts_auth.so.1` module is "sufficient" to authenticate the user. Only if this authentication fails is the next authentication module used.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `login(1)`, `rlogin(1)`, `in.rshd(1M)`, `inetd(1M)`, `pam(3PAM)`, `environ(4)`, `hosts(4)`, `hosts.equiv(4)`, `inetd.conf(4)`, `pam.conf(4)`, `attributes(5)`, `pam_rhosts_auth(5)`, `pam_unix(5)`, `ip6(7P)`

**DIAGNOSTICS** All diagnostic messages are returned on the connection associated with the `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Hostname for your address unknown.

No entry in the host name database existed for the client's machine.

Try again.

A *fork* by the server failed.

/usr/bin/sh: ...

The user's login shell could not be started.

**NOTES** The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

| <b>NAME</b>        | <code>in.routed</code> , <code>routed</code> – network routing daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.routed</code> [-s] [-q] [-t] [-g] [-S] [-v] [ <i>logfile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p><code>in.routed</code> is invoked at boot time to manage the network routing tables. The routing daemon uses a variant of the Xerox NS Routing Information Protocol in maintaining up-to-date kernel routing table entries.</p> <p>In normal operation, <code>in.routed</code> listens on <code>udp(7P)</code> socket 520 (decimal) for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.</p> <p>When <code>in.routed</code> is started, it uses the <code>SIOCGIFCONF</code> <code>ioctl(2)</code> to find those directly connected interfaces configured into the system and marked “up” (the software loopback interface is ignored). If multiple interfaces are present, it is assumed the host will forward packets between networks. <code>in.routed</code> then transmits a <i>request</i> packet on each interface (using a broadcast packet if the interface supports it) and enters a loop, listening for <i>request</i> and <i>response</i> packets from other hosts.</p> <p>When a <i>request</i> packet is received, <code>in.routed</code> formulates a reply based on the information maintained in its internal tables. The <i>response</i> packet contains a list of known routes, each marked with a “hop count” metric (a count of 16, or greater, is considered “infinite”). The metric associated with each route returned, provides a metric relative to the sender.</p> <p><i>request</i> packets received by <code>in.routed</code> are used to update the routing tables if one of the following conditions is satisfied:</p> <ul style="list-style-type: none"><li>■ No routing table entry exists for the destination network or host, and the metric indicates the destination is “reachable” (that is, the hop count is not infinite).</li><li>■ The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.</li><li>■ The existing entry in the routing table has not been updated for some time (defined to be 90 seconds) and the route is at least as cost effective as the current route.</li><li>■ The new route describes a shorter route to the destination than the one currently stored in the routing tables; the metric of the new route is compared against the one stored in the table to decide this.</li></ul> <p>When an update is applied, <code>in.routed</code> records the change in its internal tables and generates a <i>response</i> packet to all directly connected hosts and networks. <code>in.routed</code> waits a short period of time (no more than 30 seconds) before modifying the kernel’s routing tables to allow possible unstable situations to settle.</p> <p>In addition to processing incoming packets, <code>in.routed</code> also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry’s metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.</p> |

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

In addition to the facilities described above, `in.routed` supports the notion of “distant” passive and active gateways. When `in.routed` is started up, it reads the file gateways to find gateways which may not be identified using the `SIOCGIFCONF` ioctl. Gateways specified in this manner should be marked `passive` if they are not expected to exchange routing information, while gateways marked `active` should be willing to exchange routing information (that is, they should have a `in.routed` process running on the machine). Routes through passive gateways are installed in the kernel’s routing tables once upon startup. They may change, depending upon routing information they receive from other gateways. Information regarding their existence is not included in any routing information transmitted. Active gateways are treated equally to network interfaces. Routing information is distributed to the gateway, and if no routing information is received for a period of time, the associated route is deleted.

The gateways is comprised of a series of lines, each in the following format:

```
< net | host > filename1 gateway filename2 metric value < passive | active >
```

The `net` or `host` keyword indicates if the route is to a network or specific host.

*filename1* is the name of the destination network or host. This may be a symbolic name located in `networks` or `hosts`, or an Internet address specified in “dot” notation; see `inet(3SOCKET)`.

*filename2* is the name or address of the gateway to which messages should be forwarded.

*value* is a metric indicating the hop count to the destination host or network.

The keyword `passive` or `active` indicates if the gateway should be treated as passive or active (as described above).

## OPTIONS

- g        Is used on internetwork routers to offer a route to the “default” destination. This is typically used on a gateway to the Internet, or on a gateway that uses another routing protocol whose routes are not reported to other local routers.
- q        Is the opposite of the `-s` option.
- s        Forces `in.routed` to supply routing information whether it is acting as an internetwork router or not.
- S        If `in.routed` is not acting as an internetwork router it will, instead of entering the whole routing table in the kernel, only enter a default route for each internetwork router. This reduces the the memory requirements without losing any routing reliability.

## in.routed(1M)

- t All packets sent or received are printed on standard output. In addition, `in.routed` will not divorce itself from the controlling terminal so that interrupts from the keyboard will kill the process. Any other argument supplied is interpreted as the name of the file in which `in.routed`'s actions should be logged. This log contains information about any changes to the routing tables and a history of recent messages sent and received which are related to the changed route.
- v Allows a logfile (whose name must be supplied) to be created showing the changes made to the routing tables with a timestamp.

**NOTES** The kernel's routing tables may not correspond to those of `in.routed` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

`in.routed` should listen to intelligent interfaces, such as an IMP, and to error protocols, such as ICMP, to gather more information.

`in.routed` initially obtains a routing table by examining the interfaces configured on a machine and the `gateways` file. It then sends a request on all directly connected networks for more routing information. `in.routed` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.routed` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by way of the `route(1M)` command. Therefore, these types of changes should not be done while `in.routed` is running. Rather, shut down `in.routed`, make the changes required, and then restart `in.routed`.

| <b>NAME</b>        | in.rshd, rshd – remote shell server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>in.rshd</b> <i>host.port</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p><i>in.rshd</i> is the server for the <i>rsh(1)</i> program. The server provides remote execution facilities with authentication based on privileged port numbers.</p> <p><i>in.rshd</i> is invoked by <i>inetd(1M)</i> each time a shell service is requested, and executes the following protocol:</p> <ol style="list-style-type: none"> <li>1. The server checks the client's source port. If the port is not in the range 0-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to <i>in.rshd</i>.</li> <li>2. The server reads characters from the socket up to a null ( \0 ) byte. The resultant string is interpreted as an ASCII number, base 10.</li> <li>3. If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the <i>stderr</i>. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 0-1023.</li> <li>4. The server checks the client's source address. If the address is associated with a host for which no corresponding entry exists in the host name data base (see <i>hosts(4)</i>), the server aborts the connection. Please refer to the SECURITY section below for more details.</li> <li>5. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the <i>client's</i> machine.</li> <li>6. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the <i>server's</i> machine.</li> <li>7. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.</li> <li>8. <i>in.rshd</i> then validates the user according to the following steps. The remote user name is looked up in the password file and a <i>chdir</i> is performed to the user's home directory. If the lookup fails, the connection is terminated. If the <i>chdir</i> fails, it does a <i>chdir</i> to / (root). If the user is not the superuser, (user ID 0), and if the <i>pam_rhosts_auth</i> PAM module is configured for authentication, the file <i>/etc/hosts.equiv</i> is consulted for a list of hosts considered "equivalent". If the client's host name is present in this file, the authentication is considered successful. See the SECURITY section below for a discussion of PAM authentication.<br/><br/>If the lookup fails, or the user is the superuser, then the file <i>.rhosts</i> in the home directory of the remote user is checked for the machine name and identity of the user on the client's machine. If this lookup fails, the connection is terminated</li> <li>9. A null byte is returned on the connection associated with the <i>stderr</i> and the command line is passed to the normal login shell of the user. (The <i>PATH</i> variable is set to <i>/usr/bin</i>.) The shell inherits the network connections established by</li> </ol> |

## in.rshd(1M)

in.rshd.

**USAGE** rshd and in.rshd are IPv6-enabled. See ip6(7P).

**SECURITY** in.rshd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.rshd. Here is a partial pam.conf file with entries for the rsh command using rhosts authentication, UNIX account management, and session management module.

|     |         |          |                                        |
|-----|---------|----------|----------------------------------------|
| rsh | auth    | required | /usr/lib/security/pam_rhosts_auth.so.1 |
| rsh | account | required | /usr/lib/security/pam_unix.so.1        |
| rsh | session | required | /usr/lib/security/pam_unix.so.1        |

If there are no entries for the rsh service, then the entries for the "other" service will be used. To maintain the authentication requirement for in.rshd, the rsh entry must always be configured with the pam\_rhosts\_auth.so.1 module.

**FILES** /etc/hosts.equiv

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** rsh(1), inetd(1M), pam(3PAM), hosts(4), inetd.conf(4), pam.conf(4), attributes(5), pam\_rhosts\_auth(5), pam\_unix(5), ip6(7P)

**DIAGNOSTICS** The following diagnostic messages are returned on the connection associated with stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 9 above (0 is returned above upon successful completion of all the steps prior to the command execution).

locuser too long

The name of the user on the client's machine is longer than 16 characters.

remuser too long

The name of the user on the remote machine is longer than 16 characters.

command too long

The command line passed exceeds the size of the argument list (as configured into the system).

Hostname for your address unknown.

No entry in the host name database existed for the client's machine.

Login incorrect.

No password file entry for the user name existed.

Permission denied.

The authentication procedure described above failed.

Can't make pipe.

The pipe needed for the `stderr` was not created.

Try again.

A *fork* by the server failed.

**NOTES**

The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

| <b>NAME</b>        | in.rwhod, rwhod – system status server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.rwhod [-m [ttl]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>in.rwhod is the server which maintains the database used by the rwho(1) and ruptime(1) programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.</p> <p>in.rwhod operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other in.rwhod servers' status messages, validating them, then recording them in a collection of files located in the directory <code>/var/spool/rwho</code>.</p> <p>The rwho server transmits and receives messages at the port indicated in the rwho service specification, see <code>services(4)</code>. The messages sent and received are defined in <code>/usr/include/protocols/rwhod.h</code> and are of the form:</p> <pre>struct outmp {     char    out_line[8];    /* tty name */     char    out_name[8];    /* user id */     long    out_time;       /* time on */ }; struct whod {     char    wd_vers;     char    wd_type;     char    wd_fill[2];     int     wd_sendtime;     int     wd_recvtime;     char    wd_hostname[32];     int     wd_loadav[3];     int     wd_boottime;     struct  whoent {         struct outmp we_utmp;         int     we_idle;     } wd_we[1024 / sizeof (struct whoent)]; };</pre> <p>All fields are converted to network byte order prior to transmission. The load averages are as calculated by the w(1) program, and represent load averages over the 5, 10, and 15 minute intervals prior to a server's transmission. The host name included is that returned by the uname(2) system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the utmpx(4) entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.</p> <p>Messages received by the rwho server are discarded unless they originated at a rwho server's port. In addition, if the host's name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by</p> |

in.rwhod(1M)

in.rwhod are placed in files named whod.hostname in the directory /var/spool/rwho. These files contain only the most recent message, in the format described above.

Status messages are generated approximately once every 3 minutes.

**OPTIONS** -m [ ttl ] Use the rwho IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If ttl is not specified in.rwhod will multicast on all interfaces but with the IP TimeToLive set to 1 (that is, packets will not be forwarded by multicast routers.) If ttl is specified in.rwhod will only transmit packets on one interface and setting the IP TimeToLive to the specified ttl.

**FILES** /var/spool/rwho/whod.\* information about other machines

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** ruptime(1), rwho(1), w(1), uname(2), services(4), utmpx(4), attributes(5)

**WARNINGS** This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the -m multicast option.

**NOTES** This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

in.rwhod should relay status information between networks. People often interpret the server dying as a machine going down.

## install(1M)

| <b>DESCRIPTION</b> | <p>install is most commonly used in “makefiles” (see make(1S)) to install a file in specific locations, or to create directories within a file system. Each file is installed by copying it into the appropriate directory.</p> <p>install uses no special privileges to copy files from one place to another. The implications of this are:</p> <ul style="list-style-type: none"><li>■ You must have permission to read the files to be installed.</li><li>■ You must have permission to copy into the destination directory.</li><li>■ You must have permission to change the modes on the final copy of the file if you want to use the -m option.</li><li>■ You must be super-user if you want to specify the ownership of the installed file with the -u or -g options. If you are not the super-user, the installed file will be owned by you, regardless of who owns the original.</li></ul> <p>install prints messages telling the user exactly what files it is replacing or creating and where they are going.</p> <p>If no options or directories (<i>dirx . . .</i>) are given, install searches a set of default directories ( /bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as <i>file</i>. When the first occurrence is found, install issues a message saying that it is overwriting that file with <i>file</i>, and proceeds to do so. If the file is not found, the program states this and exits.</p> <p>If one or more directories (<i>dirx . . .</i>) are specified after <i>file</i>, those directories are searched before the default directories.</p> |                |                                                                                                                                                                                                                    |                |                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <table><tr><td>-c <i>dira</i></td><td>Install <i>file</i> in the directory specified by <i>dira</i>, if <i>file</i> does not yet exist. If it is found, install issues a message saying that the file already exists, and exits without overwriting it.</td></tr><tr><td>-f <i>dirb</i></td><td>Force <i>file</i> to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file will be set to 755 and bin , respectively. | -f <i>dirb</i>     | Force <i>file</i> to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file will be set to 755 and bin , respectively. If the file already exists, the mode and owner will be that of the already existing file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                                                                                                                                                                                                                    |                |                                                                                                                                                                                                                                                                                                                    |

- n *dir* If *file* is not found in any of the searched directories, it is put in the directory specified in *dir*. The mode and owner of the new file will be set to 755 and *bin*, respectively.
- d Create a directory. Missing parent directories are created as required as in `mkdir -p`. If the directory already exists, the owner, group and mode will be set to the values given on the command line.
- i Ignore default directory list, searching only through the given directories (*dirx . . .*).
- m *mode* The mode of the new file is set to *mode*. Set to 0755 by default.
- u *user* The owner of the new file is set to *user*. Only available to the super-user. Set to *bin* by default.
- g *group* The group id of the new file is set to *group*. Only available to the super-user. Set to *bin* by default.
- o If *file* is found, save the “found” file by copying it to *OLDfile* in the directory in which it was found. This option is useful when installing a frequently used file such as `/bin/sh` or `/lib/saf/ttymon`, where the existing file cannot be removed.
- s Suppress printing of messages other than error messages.

**USAGE** See `largefile(5)` for the description of the behavior of `install` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `chgrp(1)`, `chmod(1)`, `chown(1)`, `cp(1)`, `make(1S)`, `mkdir(1)`, `chown(1M)`, `attributes(5)`, `largefile(5)`

installboot(1M)

**NAME** installboot – install bootblocks in a disk partition

**SPARC** `installboot bootblk raw-disk-device`

**IA** `installboot pboot bootblk raw-disk-device`

**DESCRIPTION** The `boot(1M)` program, `ufsboot`, is loaded from disk by the bootblock program which resides in the boot area of a disk partition.

The `ufs` boot objects are platform-dependent, and reside in the `/usr/platform/platform-name/lib/fs/ufs` directory. The platform name can be found using the `-i` option of `uname(1)`.

**OPERANDS**

|                        |                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bootblk</i>         | The name of the bootblock code.                                                                                                                                                                                                                            |
| <i>raw-disk-device</i> | The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are <code>c?t?d?s?</code> and <code>c?d?s?</code> for an IDE drive. |
| <i>pboot</i>           | The name of the partition boot file.                                                                                                                                                                                                                       |

**SPARC** To install a `ufs` bootblock on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:

```
example# installboot /usr/platform/`uname -i`/lib/fs/ufs/bootblk \
/dev/rdisk/c1t0d0s0
```

**IA** To install the `ufs` bootblock and partition boot program on slice 2 of target 0 on controller 1 of the platform where the command is being run, use:

```
example# installboot /usr/platform/`uname -i`/lib/fs/ufs/pboot \
/usr/platform/`uname -i`/lib/fs/ufs/bootblk /dev/rdisk/c1t0d0s2
```

**FILES** `/usr/platform/platform-name/lib/fs/ufs`  
directory where `ufs` boot objects reside.

`/platform/platform-name/ufsboot`  
second level program to boot from a disk or CD

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `od(1)`, `uname(1)`, `boot(1M)`, `init(1M)`, `kadb(1M)`, `kernel(1M)`, `reboot(1M)`, `rpc.bootparamd(1M)`, `init.d(4)`, `attributes(5)`

installboot(1M)

*Solaris 8 Advanced Installation Guide*

**SPARC** monitor(1M)

**IA** fdisk(1M), fmthard(1M)

**WARNINGS** The `installboot` utility will fail if the `bootblk`, `pboot` or `openfirmware` files do not exist or if the raw disk device is not a character device.

installer(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>NAME</b>        | installer – Solaris Web Start installer utility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <b>installer</b> [-locales <i>list</i> ] [-nodisplay] [-debug]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The <code>installer</code> utility invokes a Web Start install wizard sequence which will lead the user through a sequence of installation panels. This installer utility is found on many CDs that are shipped with Solaris and it will be found among the top level files of these CDs.</p> <p>When the installer is on a CD being accessed from a desktop file manager, the installer can be double clicked to start the installation sequence. If the user is not currently the system's root user, the root user password will be requested.</p> <p>The installer utility can also be run from other UNIX scripts. Usually, a script is used in conjunction with the utility's <code>-nodisplay</code> option.</p>                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-locales <i>list</i></code>      Selects product translations for install, corresponding to the specified list of locales if the specified locale translations are present on the installation media. Locales are supplied in a comma-separated list following the <code>-locales</code> option. An example <i>list</i> would appear as follows:</p> <p style="padding-left: 40px;"><code>installer -locales fr,de,it</code> This would install products with translations for the French, German, and Italian locales.</p> <p><code>-nodisplay</code>      Runs the install without a graphic user interface. Use the default product install unless it was modified by the <code>-locales</code> options.</p> <p><code>-debug</code>      Outputs extra information about what the install is doing. Mainly for install diagnostic purposes.</p> |
| <b>FILES</b>       | <code>/var/sadm/install/logs</code> location of installation log files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>DESCRIPTION</b> | <p>installf informs the system that a pathname not listed in the pkgmap(4) file is being created or modified. It should be invoked before any file modifications have occurred.</p> <p>When the second synopsis is used, the pathname descriptions will be read from standard input. These descriptions are the same as would be given in the first synopsis but the information is given in the form of a list. The descriptions should be in the form:</p> <pre>pathname [ftype [ major minor ] [ mode owner group ] ]</pre> <p>After all files have been appropriately created and/or modified, installf should be invoked with the -f synopsis to indicate that installation is final. Links will be created at this time and, if attribute information for a pathname was not specified during the original invocation of installf, or was not already stored on the system, the current attribute values for the pathname will be stored. Otherwise, installf verifies that attribute values match those given on the command line, making corrections as necessary. In all cases, the current content information is calculated and stored appropriately.</p>                                                                                                                                                  |          |                                                                               |    |                                                                                                                                      |    |                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                                                                                                                               |            |                                                                                                                                                                       |

| -M                 | Instruct installf not to use the \$root_path/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |          |                                                                               |    |                                                                                                                                      |    |                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                                                                                                                               |            |                                                                                                                                                                       |
| -R root_path       | Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path may be specified when installing to a client from a server (for example, /export/root/client1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |          |                                                                               |    |                                                                                                                                      |    |                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                                                                                                                               |            |                                                                                                                                                                       |
| -V fs_file         | Specify an alternative fs_file to map the client's file systems. For example, used in situations where the \$root_path/etc/vfstab file is non-existent or unreliable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |          |                                                                               |    |                                                                                                                                      |    |                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                                                                                                                               |            |                                                                                                                                                                       |

## installf(1M)

| OPERANDS |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <i>pkginst</i>  | Name of package instance with which the pathname should be associated.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|          | <i>pathname</i> | Pathname that is being created or modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|          | <i>ftype</i>    | A one-character field that indicates the file type. Possible file types include:<br><br>b           block special device<br>c           character special device<br>d           directory<br>e           a file to be edited upon installation or removal<br>f           a standard executable or data file<br>l           linked file<br>p           named pipe<br>s           symbolic link<br>v           volatile file (one whose contents are expected to change)<br>x           an exclusive directory |
|          | <i>major</i>    | The major device number. The field is only specified for block or character special devices.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|          | <i>minor</i>    | The minor device number. The field is only specified for block or character special devices.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|          | <i>mode</i>     | The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.                                                                                                                                                                                                                                                             |
|          | <i>owner</i>    | The owner of the file (for example, bin or root). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.                                                                                                                                                                                                         |
|          | <i>group</i>    | The group to which the file belongs (for example, bin or sys). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.                                                                                                                                                                                            |

**EXAMPLES****EXAMPLE 1** The use of `installf`.

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```
#create /dev/xt directory
#(needs to be done before drvinstall)
installf $PKGINST /dev/xt d 755 root sys ||
 exit 2
majno='/usr/sbin/drvinstall -m /etc/master.d/xt
-d $BASEDIR/data/xt.o -v1.0' ||
 exit 2
i=00
while [$i -lt $limit]
do
 for j in 0 1 2 3 4 5 6 7
 do
 echo /dev/xtij c $majno `expr $i ? 8 + $j`
 644 root sys |
 echo /dev/xtij=/dev/xt/ij
 done
 i=`expr $i + 1`
 [$i -le 9] && i="0$i" #add leading zero
done | installf $PKGINST - || exit 2
finalized installation, create links
installf -f $PKGINST || exit 2
```

**EXIT STATUS**

0 Successful operation.  
>0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

## installf(1M)

The `installf` command will create directories, named pipes and special devices on the original invocation. Links are created when `installf` is invoked with the `-f` option to indicate installation is complete.

Links should be specified as *path1=path2*. *path1* indicates the destination and *path2* indicates the source file.

Files installed with `installf` will be placed in the class `none`, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, `installf` must be used in one of the following forms:

```
installf -c class1 . . .
installf -f -c class1 . . .
installf -c class2 . . .
installf -f -c class2 . . .
```

| <b>setup_install_server</b>  | <pre>cdrom-mnt-pt/Solaris_8/Tools/setup_install_server [-b] install_dir_path</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>           | <p>These commands are located on slice 0 of the Solaris Software and Solaris Installer CDs. If the Solaris CD has been copied to a local disk, <code>cdrom_mnt_pt</code> is the path to the copied Solaris CD. They can be used for a variety of installation tasks.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>add_install_client</b>    | <p>There are three versions of this command. See SYNOPSIS.</p> <p>Use the following version of the <code>add_install_client</code> command to add clients for network installation (these commands update the <code>bootparams(4)</code> file). The <code>add_install_client</code> command must be run from the install server's Solaris installation image (a mounted Solaris CD or a Solaris CD copied to disk) or the boot server's boot directory (if a boot server is required). The Solaris installation image or the boot directory must be the same Solaris release that you want installed on the client.</p> <pre>cdrom-mnt-pt/Solaris_8/Tools/add_install_client [-i IP_address] [-e Ethernet_address] [-s server_name : path] [-c server_name : path] [-n [server ] : name_service [( netmask)] [-p server_name : path] host_name platform_group</pre> <p>Use the following version of the <code>add_install_client</code> command to add support for instances of a platform within a platform group to the install server. This group will be booted and configured using DHCP. The script will perform the necessary</p> |

## install\_scripts(1M)

configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the group.

```
cdrom-mnt-pt/Solaris_8/Tools/add_install_client -d [-s server:path]
[-c server:path] [-p server:path] [-t install boot image path] [-f boot file
name] platform_name platform_group
```

Use the following version of the `add_install_client` command to add a single client to the install server. This client will be booted and configured using DHCP. The script will perform the necessary configuration steps on the server, and will print the data that the user needs to add to the DHCP server for the client. The `-f` flag used above needs to be added to the existing usage as well. `-f` allows the user to specify a boot file name to be used for a given client.

```
cdrom-mnt-pt/Solaris_8/Tools/add_install_client -d [-s
server_name:path] [-c server_name:path] [-p server_name:path] [-t
install_boot_image_path] [-f boot_file_name] -e Ethernet_address platform_group
```

**add\_to\_install\_server** Use `add_to_install_server` to merge other Solaris CDs with an existing image on a Net Install Server. Each CD that can be merged (currently OS CD 2, and the Language CD) has its own `add_to_install_server` script. Do not use `add_to_install_server` scripts with CDs other than the ones with which they were delivered.

**check** Use `check` to validate the rules in a `rules` file (this is only necessary if a custom JumpStart installation is being set up).

**modify\_install\_server** Use `modify_install_server` to replace an existing net install server's miniroot with a Solaris Installation CD's miniroot. This will change the net install server's install time user interface over to the Solaris Installation CD's Web Start user interface.

An existing install image (created using `setup_install_server`) must exist prior to using the `modify_install_server` command.

**rm\_install\_client** Use `rm_install_client` to remove clients for network installation (these commands update the `bootparams(4)` file).

**setup\_install\_server** Use `setup_install_server` to copy the Solaris CD to a disk (to set up an install server) or to copy just the boot software of the Solaris CD to a disk (to set up a boot server). An install server is required to install clients over the network. A boot server is also required for network installations if the install server and clients to be installed are on different subnets (the boot server must be located on the client's subnet).

**OPTIONS** The following options are supported:

**add\_install\_client** `-c server_name:path`

This option is required only to specify a JumpStart directory for a custom JumpStart installation. `server_name` is the host name of the server with a JumpStart directory. `path` is the absolute path to the JumpStart directory.

- d  
Specify as a DHCP client.
  - e *Ethernet\_address*  
Specify the Ethernet address of the system to be installed.
  - f  
Specify the *boot\_file\_name* of the client to be installed.
  - i *IP\_address*  
Specify the IP address of the client to be installed.
  - n [*server*]: *name\_service*[(*netmask*)]  
This option specifies which name service should be used during system configuration. This sets the *ns* keyword in the *bootparams(4)* file.  
  
*name\_service*  
Valid entries are *nis*, *nisplus*, and *none*.  
  
*netmask*  
A series of four numbers separated by periods, specifying which portion of an IP address is the network part, and which is the host part.  
  
*server*  
The name of the server or IP address of the specified name service. If the server specified is on a different subnet, then the *netmask* may be needed to enable the client to contact the server.
  - p *server\_name*: *path*  
This option is the location of the user-defined *sysidcfg* file for pre-configuring system or network information. *server\_name* is either a valid host name or IP address. *path* is the absolute path to the file.
  - s *server\_name*: *path*  
This option is required only when using *add\_install\_client* from a boot server. Specify the name of the server and the absolute path of the Solaris installation image that will be used for this installation. *path* is either the path to a mounted Solaris CD or a path to a directory with a copy of the Solaris CD.
- add\_to\_install\_server** -p  
Specifies the location of the CD (containing the supplemental products) to be copied.
- s  
Allows users to select from a list only the products needing installation.
- check** -p *install\_dir\_path*  
Validates the rules file by using the *check* script from a specified Solaris installation image, instead of the *check* script from the system you are using. *install\_dir\_path* is the path to a Solaris installation image on a local disk or a mounted Solaris CD.

install\_scripts(1M)

Use this option to run the most recent version of check if your system is running a previous version of Solaris.

*-r rulesfile*

Specifies a rules file other than the one named *rules*. Using this option, the validity of a rule can be tested before integrating it into the rules file. *check* will report whether or not the rule is valid, but it will not create the *rules.ok* file necessary for a custom JumpStart installation.

modify\_install\_server -p

This option preserves the existing images miniroot in *install\_dir\_path/Solaris\_8/Tools/Boot.orig*.

setup\_install\_server -b

This option sets up the server only as a boot server.

#### OPERANDS

The following operands are supported:

add\_install\_client

*host\_name*

This is the name of the client to be installed.

*platform\_group*

Vendor-defined grouping of hardware platforms for the purpose of distributing specific software. Examples of valid platform groups are:

| System          | Platform Group |
|-----------------|----------------|
| IA              | i86pc          |
| SPARCstation 1+ | sun4c          |
| SPARCstation 5  | sun4m          |

Use the *uname(1)* command (with the *-m* option) to determine a system's platform group.

*platform\_name*

Use the *uname(1)* command (with the *-i* option) to determine a system's platform name.

The following example shows the use of the *uname* command to determine the system platform name for an Ultra 1:

```
uname -i
```

The system responds with:

```
SUNW,Ultra-1
```

Therefore, the system's platform name is *SUNW,Ultra1*.

The following command calls *add\_install\_client* for Ultra 1s:

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>add_install_client</b>    | <p><b>EXAMPLE 1</b> Using add_install_client</p> <p>The following add_install_client commands add clients for network installation from a mounted Solaris CD on an install server:</p> <pre>example# cd /cdrom/cdrom0/s0/Solaris_8/Tools example# ./add_install_client system_1 sun4c example# ./add_install_client system_2 sun4m</pre> <p><b>EXAMPLE 2</b> Using add_install_client</p> <p>The following add_install_client commands add clients for network installation from a mounted Solaris CD on an install server. The -c option specifies a server and path to a JumpStart directory that has a rules file and a profile file for performing a custom JumpStart installation. Also, the Solaris CD has been copied to the /export/install directory.</p> <pre>example# cd /export/install/Solaris_8/Tools example# /add_install_client -c install_server:/jumpstart system_1 i86pc example# ./add_install_client -c install_server:/jumpstart system_2 i86pc</pre> <p><b>EXAMPLE 3</b> Using add_install_client</p> <p>The following add_install_client command adds support for a specific sun4u platform machine (8:0:20:99:88:77) using the boot file: sun4u.solaris8.</p> <pre>example# add_install_client -d -f sun4u.solaris8 -e 8:0:20:99:88:77 sun4u</pre> |
| <b>add_to_install_server</b> | <p><b>EXAMPLE 4</b> Using add_to_install_server</p> <p>The following add_to_install_server command copies the packages in all the supplemental CD's products directories to an existing install server:</p> <pre>example# cd /cdrom/cdrom0/s0 example# ./add_to_install_server /export/Solaris_8</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## install\_scripts(1M)

**EXAMPLE 4** Using `add_to_install_server` (Continued)

**check** **EXAMPLE 5** Using `check`

The following `check` command validates the syntax of the rules file used for a custom JumpStart installation:

```
example# cd jumpstart_dir_path
example# ./check -p /cdrom/cdrom0/s0
```

**modify\_install\_server** **EXAMPLE 6** Using `modify_install_server`

The following `modify_install_server` command replaces the miniroot created using the above `setup_install_server` with the miniroot on the Solaris Installer CD.

```
example# cd /cdrom/cdrom0/s0
example# ./modify_install_server /export/install /cdrom/cdrom0/s1
```

**EXAMPLE 7** Using `modify_install_server`

The following `modify_install_server` command moves the miniroot created using the above `setup_install_server` to `Boot.orig` and replaces it with the miniroot on the Solaris Installer CD.

```
example# cd /cdrom/cdrom0/s0
example# ./modify_install_server -p /export/install /cdrom/cdrom0/s1
```

**rm\_install\_client** **EXAMPLE 8** Using `rm_install_client`

The following `rm_install_client` commands remove clients for network installation:

```
example# cd /export/install/Solaris_8/Tools
example# ./rm_install_client holmes
example# ./rm_install_client watson
```

**setup\_install\_server** **EXAMPLE 9** Using `setup_install_server` commands

The following `setup_install_server` command copies the mounted Solaris CD to a directory named `/export/install` on the local disk:

```
example# cd /cdrom/cdrom0/s0/Solaris_8/Tools
example# ./setup_install_server /export/install
```

**EXAMPLE 10** Using `setup_install_server`

The following `setup_install_server` command copies the boot software of a mounted Solaris CD to a directory named `/boot_dir` on a system that is going to be a boot server for a subnet:

**EXAMPLE 10** Using `setup_install_server` (Continued)

```
example# cd /cdrom/cdrom0/s0/Solaris_8/Tools
example# ./setup_install_server -b /boot_dir
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
1 An error has occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | Solaris CD      |

*Solaris 8 Advanced Installation Guide*

in.talkd(1M)

**NAME** in.talkd, talkd – server for talk program

**SYNOPSIS** **in.talkd**

**DESCRIPTION** talkd is a server used by the talk(1) program. It listens at the UDP port indicated in the “talk” service description; see services(4). The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** talk(1), inetd(1M), services(4), attributes(5)

**NOTES** The protocol is architecture dependent.

| <b>NAME</b>        | in.telnetd, telnetd – DARPA TELNET protocol server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/in.telnetd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p><code>in.telnetd</code> is a server that supports the DARPA standard TELNET virtual terminal protocol. <code>in.telnetd</code> is normally invoked in the internet server (see <code>inetd(1M)</code>), for requests to connect to the TELNET port as indicated by the <code>/etc/services</code> file (see <code>services(4)</code>).</p> <p><code>in.telnetd</code> operates by allocating a pseudo-terminal device for a client, then creating a login process which has the slave side of the pseudo-terminal as its standard input, output, and error. <code>in.telnetd</code> manipulates the master side of the pseudo-terminal, implementing the TELNET protocol and passing characters between the remote client and the login process.</p> <p>When a TELNET session starts up, <code>in.telnetd</code> sends TELNET options to the client side indicating a willingness to do <i>remote echo</i> of characters, and to <i>suppress go ahead</i>. The pseudo-terminal allocated to the client is configured to operate in “cooked” mode, and with XTABS, ICRNL and ONLCR enabled. See <code>termio(7I)</code>.</p> <p><code>in.telnetd</code> is willing to do: <i>echo</i>, <i>binary</i>, <i>suppress go ahead</i>, and <i>timing mark</i>.<br/> <code>in.telnetd</code> is willing to have the remote client do: <i>binary</i>, <i>terminal type</i>, <i>terminal size</i>, <i>logout option</i>, and <i>suppress go ahead</i>.</p> <p><code>in.telnetd</code> also allows environment variables to be passed, provided that the client negotiates this during the initial option negotiation. The DISPLAY environment variable may be sent this way, either by the TELNET general environment passing methods, or by means of the XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the same negotiation where XDISPLOC is used. Note that if you use both methods, use the same value for both. Otherwise, the results may be unpredictable.</p> <p>These options are specified in Internet standards RFC 1096, RFC 1408, RFC 1571, and RFC 1572.</p> <p>The banner printed by <code>in.telnetd</code> is configurable. The default is (more or less) equivalent to “uname -sr” and will be used if no banner is set in <code>/etc/default/telnetd</code>. To set the banner, add a line of the form</p> <pre>BANNER="...to /etc/default/telnetd. Nonempty banner strings are fed to shells for evaluation. The default banner may be obtained by</pre> <pre>BANNER="\r\n\r\n'uname -s' 'uname -r'\r\n\r\n"and no banner will be printed if /etc/default/telnetd contains</pre> <pre>BANNER=""</pre> |
| <b>USAGE</b>       | <code>telnetd</code> and <code>in.telnetd</code> are IPv6-enabled. See <code>ip6(7P)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## in.telnetd(1M)

**SECURITY** | `in.telnetd` uses `pam(3PAM)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.telnetd`. Here is a partial `pam.conf` file with entries for the `telnet` command using the UNIX authentication, account management, session management, and password management modules.

|        |          |          |                                 |
|--------|----------|----------|---------------------------------|
| telnet | auth     | required | /usr/lib/security/pam_unix.so.1 |
| telnet | account  | required | /usr/lib/security/pam_unix.so.1 |
| telnet | session  | required | /usr/lib/security/pam_unix.so.1 |
| telnet | password | required | /usr/lib/security/pam_unix.so.1 |

If there are no entries for the `telnet` service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

**FILES** | `/etc/default/telnetd`

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `telnet(1)`, `inetd(1M)`, `pam(3PAM)`, `inetd.conf(4)`, `pam.conf(4)`, `services(4)`, `attributes(5)`, `pam_unix(5)`, `ip6(7P)`, `termio(7I)`

Waitzman, D., *TELNET Window Size Option*, RFC 1073, Network Information Center, SRI International, Menlo Park, Calif., October 1988.

**NOTES** Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems.

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

`in.telnetd` never sends TELNET *go ahead* commands.

in.tftpd(1M)

**NAME** in.tftpd, tftpd – Internet Trivial File Transfer Protocol server

**SYNOPSIS** **in.tftpd** [-s] [*homedir*]

**DESCRIPTION** tftpd is a server that supports the Internet Trivial File Transfer Protocol (TFTP). This server is normally started by inetd(1M) and operates at the port indicated in the tftp Internet service description in the /etc/inetd.conf file. By default, the entry for in.tftpd in etc/inetd.conf is commented out. To make in.tftpd operational, the comment character(s) must be deleted from the file. See inetd.conf(4).

Before responding to a request, the server attempts to change its current directory to *homedir*; the default directory is /tftpboot.

The use of tftp does not require an account or password on the remote system. Due to the lack of authentication information, in.tftpd will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of “public” to include all users on all hosts that can be reached through the network; this may not be appropriate on all systems, and its implications should be considered before enabling this service.

in.tftpd runs with the user ID and group ID set to [GU] ID\_NOBODY under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.

**OPTIONS** -s Secure. When specified, the directory change to *homedir* must succeed. The daemon also changes its root directory to *homedir*.

**FILES** /etc/inetd.conf

**USAGE** The in.tftpd server is IPv6-enabled. See ip6(7P).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**NAME** in.tnamed, tnamed – DARPA trivial name server

**SYNOPSIS** `/usr/sbin/in.tnamed [-v]`

**DESCRIPTION** in.tnamed is a server that supports the DARPA Name Server Protocol. The name server operates at the port indicated in the “name” service description (see `services(4)`), and is invoked by `inetd(1M)` when a request is made to the name server.

**OPTIONS** `-v` Invoke the daemon in verbose mode.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `uucp(1C)`, `inetd(1M)`, `services(4)`, `attributes(5)`

Postel, Jon, *Internet Name Server*, IEN 116, SRI International, Menlo Park, California, August 1979.

**NOTES** The protocol implemented by this program is obsolete. Its use should be phased out in favor of the Internet Domain Name Service (DNS) protocol.

| <b>NAME</b>                   | in.uucpd, uucpd – UUCP server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                             |                                 |                             |                                 |                               |                    |          |                                 |      |         |          |                                 |
| <b>SYNOPSIS</b>               | <code>/usr/sbin/in.uucpd [-n]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                             |                                 |                             |                                 |                               |                    |          |                                 |      |         |          |                                 |
| <b>DESCRIPTION</b>            | <p>in.uucpd is the server for supporting UUCP connections over networks.</p> <p>in.uucpd is invoked by inetd(1M) when a UUCP connection is established (that is, a connection to the port indicated in the “uucp” service specification) and executes the following protocol. See services(4):</p> <ol style="list-style-type: none"><li>1. The server prompts with <code>login:.</code> The uucico(1M) process at the other end must supply a username.</li><li>2. Unless the username refers to an account without a password, the server then prompts with <code>Password:.</code> The uucico process at the other end must supply the password for that account.</li></ol> <p>If the username is not valid, or is valid but refers to an account that does not have <code>/usr/lib/uucp/uucico</code> as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, uucico is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables <code>USER</code> and <code>LOGNAME</code> set to the specified username, and with a <code>-u</code> flag specifying the username. Unless the <code>-n</code> flag is specified, entries are made in <code>/var/adm/utmpx</code>, <code>/var/adm/wtmpx</code>, and <code>/var/adm/lastlog</code> for the username. in.uucpd must be invoked by a user with appropriate privilege (usually root) in order to be able to verify that the password is correct.</p> |                             |                                 |                             |                                 |                               |                    |          |                                 |      |         |          |                                 |
| <b>SECURITY</b>               | <p>in.uucpd uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for in.uucpd. Here is a partial pam.conf file with entries for uucp using the UNIX authentication, account management, and session management module.</p> <table><tr><td>uucp</td><td>auth</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr><tr><td>uucp</td><td>account</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr><tr><td>uucp</td><td>session</td><td>required</td><td>/usr/lib/security/pam_unix.so.1</td></tr></table> <p>If there are no entries for the uucp service, then the entries for the “other” service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | uucp                        | auth                            | required                    | /usr/lib/security/pam_unix.so.1 | uucp                          | account            | required | /usr/lib/security/pam_unix.so.1 | uucp | session | required | /usr/lib/security/pam_unix.so.1 |

| <b>NAME</b>        | iostat – report I/O statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/bin/iostat [-cCdDeEImMnpPrstxz] [-l <i>n</i>] [-T u   d] [<i>disk...</i>]<br/>[<i>interval</i> [<i>count</i>]]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>iostat</code> utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.</p> <p>To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, <code>iostat</code> produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. <code>iostat</code> reports this as one or more of the following messages:</p> <pre><i>device_name</i> added<br/><i>device_name</i> removed<br/><i>NFS_filesystem</i> mounted<br/><i>NFS_filesystem</i> unmounted<br/>cpu[s] taken offline: <i>cpuid</i><br/>cpu[s] brought online: <i>cpuid</i></pre> <p>where <i>device_name</i>, <i>NFS_filesystem</i> and <i>cpuid</i> are replaced with the actual name or names of the entities formatted according to other options.</p> <p>For more general system statistics, use <code>sar(1)</code>, <code>sar(1M)</code>, or <code>vmstat(1M)</code>.</p> <p>See <i>Solaris Transition Guide</i> for device naming conventions for disks.</p> |
| <b>OPTIONS</b>     | <p>The <code>iostat</code> utility's activity class options default to <code>tdc</code> (terminal, disk, and CPU). If any activity class options are specified, the default is completely overridden. Therefore, if only <code>-d</code> is specified, neither terminal nor CPU statistics will be reported. The last disk option specified (<code>-d</code>, <code>-D</code>, or <code>-x</code>) is the only one that is used.</p> <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-c</code> Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling.</li><li><code>-C</code> When the <code>-n</code> and <code>-x</code> options are also selected, report extended disk statistics aggregated by <i>controller id</i>.</li><li><code>-d</code> For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|             |                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -D          | For each disk, report the reads per second, writes per second, and percentage disk utilization.                                                                                                                               |
| -e          | Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.                                                                                                      |
| -E          | Display all device error statistics.                                                                                                                                                                                          |
| -I          | Report the counts in each interval, rather than rates (where applicable).                                                                                                                                                     |
| -l <i>n</i> | Limit the number of disks included in the report to <i>n</i> ; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see <i>disk</i> below) are not subject to this disk limit. |
| -m          | Report file system mount points. This option is most useful if the -P or -p option is also specified.                                                                                                                         |
| -M          | Display data throughput in MB/sec instead of KB/sec.                                                                                                                                                                          |
| -n          | Display names in descriptive format (for example, cXtYdZ, rmt/N, server:/export/path).                                                                                                                                        |
| -p          | For each disk, report per-partition statistics in addition to per-device statistics.                                                                                                                                          |
| -P          | For each disk, report per-partition statistics only, no per-device statistics.                                                                                                                                                |
| -r          | Display data in a comma-separated format.                                                                                                                                                                                     |
| -s          | Suppress messages related to "state changes."                                                                                                                                                                                 |
| -t          | Report the number of characters read and written to terminals per second.                                                                                                                                                     |
| -T u   d    | Emit a time stamp.<br><br>Specify <i>u</i> for a printed representation of the internal representation of time. See <code>time(2)</code> . Specify <i>d</i> for standard date format. See <code>ctime(3C)</code> .            |
| -x          | For each disk, report extended disk statistics. The output is in tabular form.                                                                                                                                                |
| -z          | Do not print lines whose underlying data values are all zeroes.                                                                                                                                                               |

**OPERANDS** The following operands are supported:

|              |                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>disk</i>  | Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see -l above) will also be reported. |
| <i>count</i> | Only print <i>count</i> reports.                                                                                                                            |

## iostat(1M)

*interval* Report once each *interval* seconds.

### EXAMPLES

#### EXAMPLE 1 Using the iostat command

```
example% iostat -xtc 5 2
 extended device statistics tty cpu
device r/s w/s kr/s kw/s wait actv svc_t %w %b tin tout us sy wt id
sd0 0.4 0.3 10.4 8.0 0.0 0.0 36.9 0 1 0 10 0 0 1 99
sd1 0.0 0.0 0.3 0.4 0.0 0.0 35.0 0 0
sd6 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs2 0.0 0.0 0.0 0.1 0.0 0.0 35.6 0 0

 extended device statistics tty cpu
device r/s w/s kr/s kw/s wait actv svc_t %w %b tin tout us sy wt id
sd0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0 0 155 0 0 0 100
sd1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
sd6 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs1 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
nfs2 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0
```

device name of the disk  
r/s reads per second  
w/s writes per second  
Kr/s kilobytes read per second  
Kw/s kilobytes written per second  
wait average number of transactions waiting for service (queue length)  
actv average number of transactions actively being serviced (removed from the queue but not yet completed)  
svc\_t average service time, in milliseconds  
%w percent of time there are transactions waiting for service (queue non-empty)  
%b percent of time the disk is busy (transactions in progress)

#### EXAMPLE 2 Using the iostat command

```
example% iostat -xnp extended device statistics
r/s w/s kr/s kw/s wait actv wsvc_t asvc_t %w %b device
0.4 0.3 10.4 7.9 0.0 0.0 0.0 36.9 0 1 c0t0d0
0.3 0.3 9.0 7.3 0.0 0.0 0.0 37.2 0 1 c0t0d0s0
0.0 0.0 0.1 0.5 0.0 0.0 0.0 34.0 0 0 c0t0d0s1
0.0 0.0 0.0 0.1 0.0 0.0 0.6 35.0 0 0 expositor:/export/home3/user3
```

The fields have the same meanings as in the previous example, with the following additions:

**EXAMPLE 2** Using the `iostat` command (Continued)

```

wsvc_t average service time in wait queue, in milliseconds
asvc_t average service time active transactions, in
 milliseconds

```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `sar(1)`, `sar(1M)`, `vmstat(1M)`, `time(2)`, `ctime(3C)`, `attributes(5)`

*Solaris Transition Guide System Administration Guide, Volume 1*

**NOTES** The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

## ipseccnf(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b> | <p>The ipseccnf utility configures the IPsec policy for a host. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host. If no entry is found, no policy checks will be completed, and all the traffic will pass through. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See <code>ifconfig(1M)</code> and <code>tun(7M)</code> for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.</p> <p>This command can be run only by superuser. Each entry protects traffic only in one direction, that is, either outbound or inbound. Thus to protect traffic in both directions, you need to have one entry in each direction.</p> <p>When the command is issued without any arguments, the policies configured in the system are shown. Each entry is displayed with an <i>index</i> followed by a number. You can use the <code>-d</code> option with the <i>index</i> to delete a given policy in the system. The entries are displayed in the order that they were added, which is not necessarily the order that the traffic match will take place. To view the order in which the traffic match will take place, use <code>-l</code> option.</p> <p>Policy entries are not preserved across reboot. Thus the policy needs to be added everytime the machine reboots. To configure policies early in the boot, one can setup policies in the <code>/etc/inet/ipseccnf.conf</code> file, which are then read from the <code>inetinit</code> startup script.</p> <p>See SECURITY CONSIDERATIONS.</p> |
| <b>OPTIONS</b>     | <p>ipseccnf supports the following options:</p> <p><code>-a file</code> Add the IPSEC policy to the system as specified by each entry in the <i>file</i>. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.</p> <p>Entries in the files are described in the OPERANDS section below. Examples can be found in the EXAMPLES section below.</p> <p>Policy is latched for TCP/UDP sockets on which a <code>connect(3SOCKET)</code> or <code>accept(3SOCKET)</code> is issued. So, addition of new policy entries may not affect such endpoints/sockets. Also, an old connection that was not subject to any policy, may be</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

subject to policy checks by the addition of new policy entries. This could disrupt the old communication if the other end is not expecting similar policy. Thus, make sure that there are not any pre-existing connections that would be subject to checks by the new policy entries.

The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.

- d *index* Delete the policy denoted by the *index*. The *index* is obtained by viewing the policy configured in the system. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that for connections whose policy has been latched, packets will continue to go out with the same policy even it has been deleted.
- f Flush all the policies in the system. Constraints are similar to the -d option with respect to latching .
- l Long listing of the policy entries. When ipseccnf is invoked without any arguments, it shows the complete list of policy entries added by the user since the boot. The -l option displays the current kernel table. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy re-ordering occurred. In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.
- n Show network addresses, ports, protocols in numbers. The -n option may only be used with the -l option.
- q Quiet mode. Suppresses the warning message generated when adding policies.

**OPERANDS** Each policy entry contains 3 parts specified as follows :

{*pattern*} *action* {*properties*} Every policy entry begins on a new line and can span multiple lines. "*pattern*" specifies the traffic pattern that should be matched against the outbound and inbound datagrams. If there is a match, a specific "*action*" determined by the second argument will be taken, depending upon the "*properties*" of the policy entry. Pattern and properties are name-value pairs where name and value are separated by space, tab or newline. Multiple name-value pairs should be separated by space, tab or newline. The beginning and end of the pattern and properties are marked by "{" and "}" respectively.

## ipsecconf(1M)

Files can contain multiple policy entries. An unspecified name-value pair in the "pattern" will be considered as wildcard. Wildcard entries matches any corresponding entry in the datagram.

File can be commented by using "#" as the first character. Comments may be inserted either at the beginning or the end of a line.

The complete syntax of a policy entry is:

```
policy ::= {pattern} action {properties}

pattern ::= <pattern_name_value_pair>|
 <pattern_name_value_pair>, <pattern>

action ::= apply | permit | bypass

properties ::= <prop_name_value_pair>|
 <prop_name_value_pair>, <properties>

pattern_name_value_pair ::=
 <saddr/prefix address>|
 <smask mask>|
 <sport part>|
 <daddr/prefix address>|
 <dmask mask>|
 <dport port>|
 <ulp protocol>

address ::= <Internet dot notation> | <String recognized by gethostbyname> |
 <String recognized by getnetbyname>

prefix ::= <number>

mask ::= <0xhexdigit[hexdigit]> | <0Xhexdigit[hexdigit]> |
 <Internet dot notation>

port ::= <number>| <String recognized by getservbyname>

protocol ::= <number>| <String recognized by getprotobyname>

prop_name_value_pair ::=
 <auth_algs auth_alg>|
 <encr_algs encr_alg>|
 <encr_auth_algs auth_alg>|
 <sa sa_val>|
 <dir dir_val>

auth_alg ::= <md5 | hmac-md5 | sha | sha1 | hmac-sha | hmac-sha1 | number>

encr_alg ::= <des | des-cbc | 3des | 3des-cbc | number>

sa_val ::= shared | unique

dir_val ::= out | in

number ::= < 0 | 1 | 2 ... 9> <number>
```

Policy entries may contain the following (name value) pairs in the `pattern` field. Each (name value) pair may appear only once in given policy entry.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>saddr/plen</i> | <p>The value that follows is the source address of the datagram with the prefix length. Only <i>plen</i> leading bits of the source address of the packet will be matched. <i>plen</i> is optional.</p> <p>The source address value can be a hostname as described in <code>gethostbyname(3XNET)</code> or a network name as described in <code>getnetbyname(3XNET)</code> or a host address or network address in the Internet standard dot notation. See <code>inet_addr(3XNET)</code>.</p> <p>If a hostname is given and <code>gethostbyname(3XNET)</code> returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.</p> |
| <i>daddr/plen</i> | <p>The value that follows is the destination address of the datagram with the prefix length. Only <i>plen</i> leading bits of the destination address of the packet will be matched. <i>plen</i> is optional.</p> <p>See <i>saddr</i> for valid values that can be given. If multiple source and destination addresses are found, then policy entry covering each (source address - destination address) pair will be added to the system.</p>                                                                                                                                                                                                                                                        |
| <i>smask</i>      | <p>The value that follows is the source mask. If prefix length is given with <i>saddr</i>, this should not be given. This can be represented either in hexadecimal number with a leading <code>0x</code> or <code>0X</code>, for example, <code>0xffff0000</code>, <code>0Xffff0000</code> or in the Internet decimal dot notation, for example, <code>255.255.0.0</code> and <code>255.255.0.0</code>. The mask should be contiguous and the behavior is not defined for non-contiguous masks.</p> <p><i>smask</i> is considered only when <i>saddr</i> is given.</p>                                                                                                                                |
| <i>dmask</i>      | <p>The value that follows is the destination mask. If prefix length is given with <i>daddr</i>, this should not be given. This can be represented either in hexadecimal number with a leading <code>0x</code> or <code>0X</code>, for example, <code>0xffff0000</code>, <code>0Xffff0000</code> or in the Internet decimal dot notation, for example, <code>255.255.0.0</code> and <code>255.255.255.0</code>. The mask should be contiguous and the behavior is not defined for non-contiguous masks.</p> <p><i>dmask</i> is considered only when <i>daddr</i> is given.</p>                                                                                                                         |

## ipsecconf(1M)

|              |                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sport</i> | The value that follows is the source port of the datagram. This can be either a port number or a string searched with a <code>NULL</code> proto argument, as described in <code>getservbyname(3XNET)</code>    |
| <i>dport</i> | The value that follows is the destination port of the datagram. This can be either a port number or a string as described in <code>getservbyname(3XNET)</code> searched with <code>NULL</code> proto argument. |
| <i>ulp</i>   | The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in <code>getprotobyname(3XNET)</code>                              |

If any component of the entry is not given, it will be considered as a wildcard entry. Thus, if `pattern` is null, all packets will match the policy entry. If neither the prefix length nor the mask is given for the address, a mask will be inferred. For example, if `a.b.c.d` is the address and

- `b, c` and `d` are zeroes, the mask is `0xff000000`.
- only `c` and `d` are zeroes, the mask is `0xffff0000`.
- only `d` is zero, the mask is `0xffffffff00`.
- neither `a, b, c` nor `d` are zeroes, the mask is `0xffffffff`.

To avoid ambiguities, it is advisable to explicitly give either the prefix length or the mask.

Policy entries may contain the following (name value) pairs in the properties filed. Each (name value) pair may appear only once in a give policy entry.

|                  |                                                                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>auth_algs</i> | An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See <i>RFC 2402</i> . |
|                  | This entry can contain either a string or a decimal number.                                                                                                                                                                                                                                                       |
| <i>string</i>    | This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in <i>RFC 2403</i> , and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in <i>RFC 2404</i> . The string can also be <code>ANY</code> , which denotes no-preference                            |

|                |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |        | for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.                                                                                                                                                                                                                                                                                                                                                             |
|                | number | A number in the range 1-255. This is useful when new algorithms can be dynamically loaded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                |        | If <i>auth_algs</i> is not present, the AH header will not be present in the outbound datagram, and the same will be verified for the inbound datagram.                                                                                                                                                                                                                                                                                                                                                                                                     |
| encr_algs      |        | An acceptable value following this implies that IPsec ESP header will be present in the outbound datagram. The value following this describes the encryption algorithms that will be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present on inbound datagrams. See <i>RFC 2406</i> .                                                                                                                                                                                                                                     |
|                |        | This entry can contain either a string or a decimal number. Strings are not case-sensitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                | string | This should be either DES or DES-CBC, to denote the algorithm described in <i>RFC 2405</i> or 3DES or 3DES-CBC, to denote the used of 3DES in a manner consistent with <i>RFC 2451</i> . The value can be NULL which implies a NULL encryption pursuant to <i>RFC 2410</i> . This means that the payload will not be encrypted. The string can be ANY, which denotes no-preference for the algorithm. Default algorithms will be chosen depending upon the SAs available at this time for manual SAs and upon the key negotiating daemon for automatic SAs. |
|                | number | A decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| encr_auth_algs |        | An acceptable value following <i>encr_auth_algs</i> implies that the IPsec ESP header will be present in the outbound datagram. The values following                                                                                                                                                                                                                                                                                                                                                                                                        |

`encr_auth_algs` describe the authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2406*. This entry can contain either a string or a number. Strings are case-insensitive.

`string` Valid values are the same as the ones described for `auth_algs` above.

`number` This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded. If `encr_algs` is present and `encr_auth_algs` is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.

If `encr_algs` is not present and `encr_auth_algs` is present in a policy entry, null encryption will be provided, which is equivalent to `encr_algs` with `NULL`, for outbound and inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.

`dir`

Values following this decides whether this entry is for outbound or inbound datagram. Valid values are strings that should be one of the following.

`out` This means that this policy entry should be considered only for outbound datagrams.

`in` This means that this policy entry should be considered only for inbound datagrams.

This entry is not needed when the action is "apply" or "permit". But if it is given while the action is "apply" or "permit", it should be "out" or "in" respectively. This is mandatory when the action is "bypass".

sa

Values following this decide the attribute of the security association. Value indicates whether an unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using `ipseckey(1M)`. The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unique | Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified. |
| shared | Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is mandatory only for outbound policy entries and should not be given for entries whose action is "bypass". If this entry is not given for inbound entries, for example, when "dir" is in or "action" is permit, it will be assumed to be shared.                                                                                                                               |

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.

|        |                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apply  | Apply IPSEC to the datagram as described by the properties, if the pattern matches the datagram. If <code>apply</code> is given, the pattern is matched only on the outbound datagram.                                                                                       |
| permit | Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If <code>permit</code> is given, the pattern is matched only for inbound datagrams. |

`bypass` Bypass any policy checks if the pattern matches the datagram. `dir` in the properties decides whether the check is done on outbound or inbound datagrams. All the `bypass` entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. `dir` is the only field that should be present when action is `bypass`.

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will re-order the policy entry, that is, add the new entry before the old entry, only when:

- The level of protection is "stronger" than the old level of protection. Currently, strength is defined as:

AH and ESP > ESP > AH  
The standard uses of AH and ESP were what drove this ranking of "stronger". There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See `ipsecesp(7P)` for more details.

- If the new entry has `bypass` as action. `bypass` has the highest precedence. It can be added in any order, and the system will still match all the `bypass` entries before matching any other entries. This is useful for key management demons which can use this feature to bypass IPSEC as it protects its own traffic.

Entries with both AH (`auth_algs` present in the policy entry) and ESP (`encr_auth_algs` or `encr_auth_algs` present in the policy entry) protection are ordered after all the entries with AH and ESP and before any AH-only and ESP-only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See EXAMPLES.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See EXAMPLES for information on duplicates.

**SECURITY  
CONSIDERATIONS**

If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` has been issued. Adding new policy entries will not have any effects on them. This feature of latching may change in the future. It is advisable not to depend upon this feature.

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

#### EXAMPLES **EXAMPLE 1** Protecting Outbound TCP Traffic With ESP and the DES Algorithm

```
#
Protect the outbound TCP traffic between hosts spiderweb
and arachnid with ESP and use DES algorithm.
#
{
 saddr spiderweb
 daddr arachnid
 ulp tcp #only TCP datagrams.
} apply {
 encr_algs DES
}
```

This entry specifies that for any TCP packet from spiderweb to arachnid should be encrypted with DES and the SA could be a shared one. As no prefix len or mask is given, a mask will be inferred. To look at the mask, use the `ipseccnf` command with the `-l` option.. Note that `dir` is not given in properties as `apply` implies that only outbound packets will be matched with the pattern.

#### **EXAMPLE 2** Verifying Whether or Not Inbound Traffic is Encrypted

The above entry will not verify whether or not the inbound traffic is encrypted. Thus you need the following entry to protect inbound traffic..

```
#
Protect the TCP traffic on inbound with ESP/DES from arachnid
to spiderweb
#
{
 saddr arachnid
 daddr spiderweb
 ulp tcp
} permit {
 encr_algs DES
}
```

"sa" can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified..This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with `encr_auth_alg` specified, if it was found in the SA tables.

**EXAMPLE 3** Authenticating All Inbound Traffic to the Telnet Port

```
#
All the inbound traffic to the telnet port should be
authenticated.
#
{
 dport telnet # telnet is 23
} permit {
 auth_algs SHA1
 dir in
}
```

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. Note that `dir` as given is optional, as `permit` implies that this policy entry will be checked only on inbound. "sa" is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well.

**EXAMPLE 4** Verifying Inbound Traffic is Null-Encrypted

```
#
Make sure that all inbound traffic from network-B is NULL
encrypted, but bypass for host-B alone from that network.
Add the bypass first.
{
 saddr host-B
} bypass {
 dir in
}
Now add for network-B.
{
 saddr network-B/16
} permit {
 encr_algs ENUL
 encr_auth_algs md5
}
```

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is `bypass` it need not be given first in order, as `bypass` entries have the highest precedence. Thus any inbound traffic will be matched against all `bypass` entries before any other policy entries..

**EXAMPLE 5** Encrypting a Packet with 3DES and SHA1

The following entry on host-B specifies that that any packet from hostA to hostB should be encrypted with 3DES and SHA1.

```
{
 saddr hostA
```

**EXAMPLE 5** Encrypting a Packet with 3DES and SHA1 (Continued)

```

 daddr hostB
} permit {
 encr_algs 3DES
 encr_auth_algs SHA1
}

```

If you try to add an entry

```

{
 saddr hostA
 daddr hostB
 dport 23
} permit {
 encr_algs DES
}

```

it will fail with "ioctl:File exists". But if you change the order, that is, give the second entry first, and first entry second, it will succeed. This is because traffic to port number 23 from hostB to hostA will be protected with DES and the remainder will be protected with 3DES and SHA1.

If you modify the second entry as follows,

```

{
 saddr hostA
 daddr hostB
 dport 23
} permit {
 encr_algs DES
 auth_algs SHA1
}

```

it will not fail. This entry gets ordered first in the list, as the entry is protected with AH and ESP, which has precedence before the prior entry that has only ESP. You can add a bypass entry in any order and it will always have the highest precedence. But, all other entries are subject to the check as explained above.

The following entry

```

{
 daddr 134.56.0.0 # Network address
 dmask 0xffff0000
} permit { auth_algs any}

```

expects any traffic originating from 134.56.0.0 to be authenticated. You cannot add the following entry after the above entry has been added,

```

{
 daddr 134.56.123.0
 dmask 0xffffffff00
} permit { encr_algs any}

```

as the previous entry would match the traffic from 134.56.0.0. But you can add this entry before adding the previous entry, or you can add it with AH and ESP protection. It will be reordered and considered before the previous one.

## ipsecconf(1M)

### EXAMPLE 6 Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 500 or coming into port number 500 should not be subjected to IPsec policy checks, irrespective of any other policy entry in the system. Thus the latter two entries will be considered only for ports other than port number 500.

```
#
Bypass traffic for port no 500
#
{sport 500} bypass {dir out}
{dport 500} bypass {dir in}
{saddr spiderweb} apply { encr_algs any sa unique}
{daddr spiderweb} permit { encr_algs any}
```

### EXAMPLE 7 Protecting Outbound Traffic

```
#
Protect the outbound traffic from all interfaces.
#
{saddr spiderweb} apply {auth_algs any sa unique}
If gethostbyname ("spiderweb") yields multiple addresses, multiple policy
entries will be added for all the source address with the same properties.
```

```
{
 saddr spiderweb
 daddr arachnid
} apply { auth_algs any sa unique}
```

If `gethostbyname ("spiderweb")` and `gethostbyname ("arachnid")` yield multiple addresses, multiple policy entries will be added for each (`saddr daddr`) pair with the same properties. Use `ipsecconf -l` to view all the policy entries added here.

### EXAMPLE 8 Bypassing Unauthenticated Traffic

```
#
Protect all the outbound traffic with ESP except any traffic
to network-b which should be authenticated and bypass anything
to network-c
#
{daddr network-b/16} apply { auth_algs any }
{} apply { encr_algs any sa shared} # NULL pattern
{daddr network-c/16} bypass {dir out}
```

Note that `bypass` can be given anywhere and it will take precedence over all other entries. `NULL pattern` matches all the traffic. .

|              |                                         |                                                                                                                                        |
|--------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILES</b> | <code>/etc/inet/ipsecpolicy.conf</code> | File containing IPSEC policies configured in the system. Maintained by <code>ipsecconf</code> command. Do not manually edit this file. |
|              | <code>/etc/inet/ipsecinit.conf</code>   | File containing IPsec policies that are configured early in the boot. If present, it is                                                |

ipseconf(1M)

read from /etc/init.d/inetinit after /usr is mounted.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

**DIAGNOSTICS**

Bad "string" on line N.

Duplicate "string" on line N.

String reflects one of the names in pattern or properties is wrong. Bad indicates a malformed argument, and Duplicate indicates that there are multiple arguments of similar type. for example, multiple saddr.

Error before or at line N.

Indicates parsing error before or at line N.

Non-existent index

Reported when the *index* for delete is not a valid one.

ioctl: File exists

Reported when there is already a policy entry that matches the traffic of this new entry.

## ipseckey(1M)

| <b>DESCRIPTION</b> | <p>The ipseckey command is used to manually manipulate the security association databases of the network security services, ipsecak(7P) and ipsecesp(7P). You can use the ipseckey command to set up security associations between communicating parties when automated key management is not available.</p> <p>While the ipseckey utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See pf_key(7P). When ipseckey is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association (“SA”) type, while others permit the SA type to be unspecified and act on all SA types.</p> <p>ipseckey uses a PF_KEY socket and the message types SADB_ADD, SADB_DELETE, SADB_GET, SADB_UPDATE, SADB_FLUSH, and SADB_X_PROMISE. Thus, you must be a superuser to use this command.</p> <p>ipseckey handles sensitive cryptographic keying information. Please read the SECURITY CONSIDERATIONS section for details on how to use this command securely.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <pre>-f [<i>filename</i>] -n</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <p>Read commands from an input file, <i>filename</i>. The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.</p> <p>Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.</p> |

|          |                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMMANDS | <p>-p</p> <p>-s [<i>filename</i>]</p> <p>-v</p> <p>add</p> <p>update</p> <p>delete</p> <p>get</p> <p>flush</p> <p>monitor</p> <p>passive_monitor</p> <p>pmonitor</p> <p>dump</p> | <p>Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.</p> <p>The opposite of the -f option. If '-' is given for a <i>filename</i>, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the -f option. The output will be a series of add commands.</p> <p>Verbose. Print the messages being sent into the PF_KEY socket, and print raw seconds values for lifetimes.</p> <p>Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the command line. The add command accepts all extension-value pairs described below.</p> <p>Update SA lifetime, and in the cases of larval SAs (leftover from faulty automated key management), keying material and other extensions. Like add, this command cannot be invoked from the command line because keying material could be seen by the ps(1) command. The update command accepts all extension-value pairs, but normally is only used for SA lifetime updates.</p> <p>Delete a specific SA from a specific SADB. This command requires the spi extension, and the dest extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message.</p> <p>Lookup and display a security association from a specific SADB. Like delete, this command only requires spi and dest for IPsec.</p> <p>Remove all SA for a given SA_TYPE, or all SA for all types.</p> <p>Continuously report on any PF_KEY messages. This uses the SADB_X_PROMISC message to enable messages that a normal PF_KEY socket would not receive to be received.. See pf_key(7P).</p> <p>Like monitor, except that it does not use the SADB_X_PROMISC message.</p> <p>Synonym for passive_monitor.</p> <p>Will display all SAs for a given SA type, or will display all SAs. Because of the large amount of data generated by this command, there is no guarantee that all SA</p> |

ipseckey(1M)

**SECURITY  
ASSOCIATION  
TYPES**

|      |                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      | information will be successfully delivered, or that this command will even complete.                                                                                                   |
| save | Is the command analog of the <code>-s</code> option. It is included as a command to provide a way to snapshot a particular SA type, for example, <code>esp</code> or <code>ah</code> . |
| help | Prints a brief summary of commands.                                                                                                                                                    |
| all  | Specifies all known SA types. This type is only used for the <code>flush</code> and <code>dump</code> commands. This is equivalent to having no SA type for these commands.            |
| ah   | Specifies the IPsec Authentication Header ("AH") SA.                                                                                                                                   |
| esp  | Specifies the IPsec Encapsulating Security Payload ("ESP") SA.                                                                                                                         |

**EXTENSION  
VALUE TYPES**

Commands like `add`, `delete`, `get`, and `update` require that certain extensions and associated values be specified. The extensions will be listed here, followed by the commands that use them, and the commands that require them. Requirements are currently documented based upon the IPsec definitions of an SA. Required extensions may change in the future. `<number>` can be in either hex (`0xnnn`), decimal (`nnn`) or octal (`0nnn`). `<string>` is a text string. `<hexstr>` is a long hexadecimal number with a bit-length. Extensions are usually paired with values; however, some extensions require two values after them.

`spi <number>`  
Specifies the security parameters index of the SA. This extension is required for the `add`, `delete`, `get` and `update` commands.

`replay <number>`  
Specifies the replay window size. If not specified, the replay window size is assumed to be zero. It is not recommended that manually added SAs have a replay window. This extension is used by the `add` and `update` commands.

`state <string> | <number>`  
Specifies the SA state, either by numeric value or by the strings "larval", "mature", "dying" or "dead". If not specified, the value defaults to mature. This extension is used by the `add` and `update` commands.

`auth_alg <string> | <number>`  
`authalg <string> | <number>`  
Specifies the authentication algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current authentication algorithms include:

|           |                                 |
|-----------|---------------------------------|
| HMAC-MD5  | md5, hmac-md5                   |
| HMAC-SH-1 | sha, sha-1, hmac-sha1, hmac-sha |

Often, algorithm names will have several synonyms. This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

`encr_alg <string> | <number>`

`encralg <string> | <number>`

Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES ("des") and Triple-DES ("3des"). This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

The next six extensions are lifetime extensions. There are two varieties, "hard" and "soft". If a hard lifetime expires, the SA will be deleted automatically by the system. If a soft lifetime expires, an `SADB_EXPIRE` message will be transmitted by the system, and its state will be downgraded to `dying` from `mature`. See `pf_key(7P)`. The `monitor` command to `key` allows you to view `SADB_EXPIRE` messages.

`soft_bytes <number>`

`hard_bytes <number>`

Specifies the number of bytes that this SA can protect. If `<number>` is not specified, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the `add` and `update` commands.

`soft_addtime <number>`

`hard_addtime <number>`

Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If `<number>` is not specified, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

`soft_usetime <number>`

`hard_usetime <number>`

Specifies the number of seconds this SA can exist after first being used. If `<number>` is not specified, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

`srcaddr <address>`

`src <address>`

`srcaddr <address>` and `src <address>` are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. This is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the `add`, `update`, `get` and `delete` commands.

`dstaddr <addr>`

`dst <addr>`

`dstaddr <addr>` and `dst <addr>` are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and `spi` for identification, this extension, with a specific value, is required for the `add`, `update`, `get` and `delete` commands.

## ipseckey(1M)

`proxyaddr <address>`

`proxy <address>`

`proxyaddr <address>` and `proxy <address>` are synonyms that indicate the proxy address for the SA. A proxy address is used for an SA that is protecting an inner protocol header. The proxy address is the source address of the inner protocol's header. This extension is used by the `add` and `update` commands.

`authkey <hexstring>`

Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional `/` at the end, for example, `123/12`. Bits are counted from the most-significant bits down. For example, to express three '1' bits, the proper syntax is the string `"e/3"`. For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the `add` and `update` commands.

`encrkey <hexstring>`

Specifies the encryption key for this SA. The syntax of the key is the same as `authkey`. A concrete example of a multi-key encryption algorithm is `3des`, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the `add` and `update` commands.

Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the `add` command will fail with an invalid value.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, `srcidtype` takes two values, a `type`, and an actual `value`. The type can be one of the following:

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>prefix</code>    | An address prefix.                                 |
| <code>fqdn</code>      | A fully-qualified domain name.                     |
| <code>domain</code>    | Domain name, synonym for <code>fqdn</code> .       |
| <code>user_fqdn</code> | User identity of the form <code>user@fqdn</code> . |
| <code>mailbox</code>   | Synonym for <code>user_fqdn</code> .               |

The value is an arbitrary text string, which should identify the certificate.

`srcidtype <type, value>`

Specifies a source certificate identity for this SA. This extension is used by the `add` and `update` commands.

`dstidtype <type, value>`

Specifies a destination certificate identity for this SA. This extension is used by the `add` and `update` commands.

**SECURITY  
CONSIDERATIONS**

The ipseckey command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the ipseckey command.

1. Is the TTY going over a network (interactive mode)?
  - If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using ipseckey over a clear-text telnet or rlogin session is risky.
  - Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.
2. Is the file accessed over the network or readable to the world (-f option)?
  - A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. Administrators are urged to be cautious when using ipseckey. The safest mode of operation is probably on a console, or other hard-connected TTY.

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

**EXAMPLES****EXAMPLE 1** Emptying Out All SAs

To empty out all SA:

```
example# ipseckey flush
```

**EXAMPLE 2** Flushing Out IPsec AH SAs Only

To flush out only IPsec AH SAs:

```
example# ipseckey flush ah
```

**EXAMPLE 3** Saving All SAs To Standard Output

To save all SAs to the standard output:

```
example# ipseckey save all
```

**EXAMPLE 4** Saving ESP SAs To The File /tmp/snapshot

To save ESP SAs to the file /tmp/snapshot::

```
example# ipseckey save esp /tmp/snapshot
```

## ipseckey(1M)

**EXAMPLE 4** Saving ESP SAs To The File /tmp/snapshot (Continued)

**EXAMPLE 5** Deleting an IPsec SA

To delete an IPsec SA, only the SPI and the destination address are needed:

```
example# ipseckey delete esp spi 0x2112 dst 224.0.0.1
```

**EXAMPLE 6** Getting Information on an IPsec SA

Likewise, getting information on a SA only requires the destination address and SPI:

```
example# ipseckey get ah spi 0x5150 dst mypeer
```

**EXAMPLE 7** Adding or Updating IPsec SAs

Adding or updating SAs requires entering interactive mode:

```
example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com \
 authalg md5 authkey 1234567890abcdef1234567890abcdef
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes \
 16000000
ipseckey> exit
```

**EXAMPLE 8** Adding an SA in the Opposite Direction

In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

```
example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com \
 authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
 hard_bytes 16000000
ipseckey> exit
```

**EXAMPLE 9** Monitoring PF\_KEY Messages

Monitoring for PF\_KEY messages is straightforward:

```
example# ipseckey monitor
```

**EXAMPLE 10** Using Commands in a File

Commands can be placed in a file that can be parsed with the `-f` option. This file may contain comment lines that begin with the `"#"` symbol. For example:

```
This is a sample file for flushing out the ESP table and
adding a pair of SAs.

flush esp
```

**EXAMPLE 10** Using Commands in a File (Continued)

```
Watch out! I have keying material in this file. See the
SECURITY CONSIDERATIONS section in this manual page for why this can be
dangerous.

add esp spi 0x2112 src me.domain.com dst you.domain.com \
 authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
 encralg des encrkey be02938e7def2839 hard_usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com \
 authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 \
 encralg des encrkey 8bd4a52e10127deb hard_usetime 28800

End of file - This is a gratuitous comment
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

**SEE ALSO** ps(1), ipsecconf(1M), route(1M), attributes(5), ipsec(7P), ipsecah(7P), ipsecesp(7P), pf\_key(7P)

**DIAGNOSTICS**

- Parse error on line N.  
If an interactive use of ipseckey would print usage information, this would print instead. Usually preceded by another diagnostic.
- Unexpected end of command line.  
An additional argument was expected on the command line.
- Unknown  
A value for a specific extension was unknown.
- Address type N not supported.  
A name-to-address lookup returned an unsupported address family.
- is not a bit specifier
- bit length N is too big for
- string is not a hex string  
Keying material was not entered appropriately.
- Can only specify single  
A duplicate extension was entered.
- Don't use extension for <string> for <command>.  
An extension not used by a command was used.

## ipseckey(1M)

**NOTES** | In spite of its IPsec-specific name, `ipseckey` is analogous to `route(1M)`, in that it is a command-line interface to a socket-based administration engine, in this case, `PF_KEY`. `PF_KEY` was originally developed at the United States Naval Research Laboratory.

To have machines communicate securely with manual keying, SAs need to be added by all communicating parties. If two nodes wish to communicate securely, both nodes need the appropriate SAs added.

If the `-n` flag is not used when saving SAs, the resulting name for an address may not directly map to the address of an SA. In the future `ipseckey` may be invoked under additional names as other security protocols become available to `PF_KEY`.

| <b>DESCRIPTION</b> | <p>kadb is an interactive kernel debugger with a user interface similar to adb(1), the assembly language debugger.</p> <p>kadb must be loaded prior to the standalone program it is to debug. kadb runs with the same environment as the standalone program, so it shares many resources with that program. The debugger is cognizant of and able to control multiple processors, should they be present in a system.</p> <p>When kadb is started, it requests the default filename from boot(1M), and if loaded non-interactively (without the -d option), it loads the default filename.</p> <p>On systems which support both 32-bit and 64-bit operating system, boot(1M) chooses an appropriate default filename for that system. If loaded interactively (by specifying the -d option), kadb prompts with the default filename, which can be changed before continuing. The default filename can be specified on the boot(1M) command line. See boot(1M) for details.</p> <p>Before loading the 64-bit kernel explicitly, review the information in boot(1M) for restrictions on running the 64-bit kernel on certain configurations.</p> <p>Unlike adb(1), kadb runs in the same supervisor virtual address space as the program being debugged, although it maintains a separate context. The debugger runs as a <i>co-process</i> that cannot be killed (no :k command as in adb) or rerun (no :r command as in adb). There is no signal control (no :i, :t, or \$i commands as in adb), although the keyboard facilities (CTRL-C, CTRL-S, and CTRL-Q) are simulated.</p> <p>In the case of the UNIX system kernel, the keyboard abort sequence suspends kernel operations and breaks into the debugger. This behavior may be disabled by way of the kbd(1) command and may not be the current default on all systems. See kb(7M) for more information.</p> <p>As the kernel is composed of the core image file and the set of loadable modules already in memory, kadb has the capability of debugging all of these by traversing special data structures. kadb makes use of this feature to allow it to reference any kernel data structure, even if it resides in a loadable module. kadb sets the -d flag by default so the program being debugged can tell it is being watched. If this flag is not given, kadb loads and immediately runs the default kernel.</p> <p>Most adb(1) commands function in kadb as they do in adb. As with adb -k, \$p works when debugging kernels. The verbs ? and / are equivalent in kadb, as there is only one address space in use.</p> |

## kadb(1M)

The keyboard abort sequence is L1+A on keyboards with an L1 key, and F1+A on keyboards with no L1 key. On serial lines, the default abort sequence is a BREAK signal, but this can be changed to the sequence “carriage return, tilde, control&hyphen;B” using:

```
kbd -a alternate
```

See kbd(1).

Once aborted, kadb responds with the following:

```
kadb [cpu] :
```

where *cpu* is the number of the CPU on which kadb is currently executing.

**OPTIONS** The following options are supported:

-d Interactive startup. If specified, kadb stops after loading and displays the kadb: prompt, followed by the name of the default program to debug.

The user may either press RETURN to debug the default program, or BACK SPACE followed by the name of another program to debug.

**OPERANDS** The following operands are supported:

*boot-flags* Specifies boot flags as arguments to kadb. The specified boot-flags are passed to the program being debugged. See boot(1M) for available boot-flags.

**SPARC Only** *device-specifier* Specifies the device from which to load. See monitor(1M).

**Kernel Macros** As with adb(1), kernel macros can be used with kadb, but they cannot be read from a file at runtime. Use the kadb \$M command to list all of the built-in kadb macros.

**Commands** kadb reads commands from the standard input and displays responses on the standard output. kadb supports the majority of the adb(1) commands. kadb does not support the following adb commands: :k, :r, :i, :t, or \$i. See adb(1).

Additionally, kadb supports the following commands:

[  
Performs the same function as :e in adb(1), but requires only one keystroke and no RETURN (ENTER on IA based systems).

]  
Performs the same function as :s in adb(1), but requires only one keystroke and no RETURN (ENTER on IA based systems).

**:a**

Sets a hardware access (read or write) breakpoint using the processor hardware facilities. The syntax and action for this command is the same as the **:b** command in **adb**, with the following exceptions:

- The breakpoint triggers if any bytes from the breakpoint for length bytes are being accessed. See §1 below for setting the length of a hardware breakpoint.
- Breakpoints should be aligned for the length specified. Any address is valid for length 1. Addresses divisible by 2 should be used for length 2 (short). Addresses divisible by 4 should be used for length 4 (int).
- Detection of an access breakpoint occurs after completion of the instruction that caused it.
- There are a limited number (4) of hardware breakpoint registers, and, when set, this uses one.
- As this breakpoint does not modify memory locations, this command will work on locations that are not in core at the time the breakpoint is set.

**@fmt**

Used in the same manner as the **adb /** and **?** commands. Specify **@** as a physical memory address as opposed to the normal virtual address. Specify **fmt** as any of the formats used with the **adb /** command. This command is useful for displaying memory that may not be mapped, for example, **kernel** page tables or buffers used for DMA by device drivers.

**function:: call arg1, arg2, arg3, ...**

Invokes kernel functions with 0 or more arguments. Using this command results in a response such as:

```
retval = function(arg1,arg2,arg3,...);
```

where *retval* is the return value of the function. This feature can be error prone, as functions may have side effects that cause failures if the kernel is continued.

**:p**

Sets a hardware access (read or write) breakpoint using the processor hardware facilities when an instruction at the specified address is run. The §1 operation has no effect on this type of breakpoint. This breakpoint occurs before the instruction is executed.

**:P**

Works as **:a**, but this command will only breakpoint when an access is made to the address in IA I/O space. See **:a**.

**:w**

Sets a write hardware access breakpoint using the processor hardware facilities.

**[length]§1**

Sets the default data length for an access or write breakpoint. *length* can be set to 1 for byte, 2 for short, and 4 for int word accesses. If *length* is not specified, 1 byte is

kadb(1M)

assumed. Once set, this value affects any newly set access or write breakpoints, but does not affect ones set before this operation.

\$b

Displays two additional columns that *kadb* does not. The first is the *type* column which indicates *soft* for a normal breakpoint, *access* for an access hardware breakpoint, *write* for a write hardware breakpoint, and *inst* for an instruction hardware breakpoint. The second is the *len* column which for access and write breakpoints indicate the length of the operation to break on.

**SPARC**

\$q Gives control to the boot prom, from which you may reboot the system.

*cpu*:*x* Switches the active CPU to *cpu*. Thereafter, commands such as \$*r* and \$*c* displays the registers and stack of the new CPU, *cpu*.

**IA**

*port*:*i* Inputs a byte for display from *port*. *port* is an address-specified I/O port. For example, 330:*i* inputs from address port 330.

*port*:*i*8 Same as the *:i* command. See *:i*.

*port*:*i*16 Inputs two bytes for display from *port*. *port* is an address-specified I/O port.

*port*:*i*32 Inputs four bytes for display from *port*. *port* is an address-specified I/O port.

*port,data*:*o* Outputs a byte to *port*. *port* is an address-specified I/O port. [*address*], [*data*]:*o* outputs the value *data* to address I/O *port*. For example, 330, 80:*o* outputs 80 to address port 330.

*port,data*:*o*8 Same as the *:o* command. See *port,data*:*o*.

*port,data*:*o*16 Outputs two bytes to *port*. *port* is an address-specified I/O port.

*port,data*:*o*32 Outputs four bytes to *port*. *port* is an address-specified I/O port.

\$q

Prompts the user with:

Type 'y' if you really want to reboot. Responding with a y or Y causes the system to reboot. Responding with anything other than a y or Y returns control to *kadb*. Use this feature when you cannot press the *reset* switch on your machine. Because using \$q may result in data loss, this command should only be used when you would press the *reset* switch or power off your system.

**Online Help Commands**

::help Displays the formats of *kadb* commands and extended commands.

::? Same as the ::help command. See ::help.

::morehelp Displays additional information about commonly used commands and provides an explanation of data formats.

**Scroll Control Feature**`num::more`

A common problem with using `kadb` is that scrolling is sometimes too fast and that CTRL-s and CTRL-q are inexact controls. A conditional scroll control feature similar to `more(1)` has been added to `kadb`. To enable this feature, the user specifies the number of lines to be displayed, followed by `::more`. For example, the command `14::more` displays 14 (current radix) lines, followed by the `--More--` prompt. At this prompt, press: ENTER or RETURN to display one more line. Press `c`, `C`, or CTRL-c to interrupt the display. Press any other key to display the next `num` number of specified lines (14 in this example). The command `::more` displays the current setting for the number of lines that `kadb` displays before printing the `--More--` prompt. The initial scroll control value of this feature is 0, meaning that scrolling is disabled. Once enabled, the `0::more` command disables the scroll control feature.

**Deferred Breakpoint Feature**

Since the kernel is dynamically loaded, not all modules may be loaded when a breakpoint is set. `kadb` can set *deferred* breakpoints which will be dynamically inserted when the corresponding module is loaded. The module and the location must both be specified when referring to a deferred breakpoint, as follows:

```
module_name#location:
```

This syntax is implemented for `kadb` only and uses existing breakpoint commands (for example, `ufs#ufs_open:b` or `ufs#ufs_open+4,5:b`).

If the module has been loaded, `kadb` attempts to find the symbol in the module specified. If `kadb` finds the symbol, it sets a regular breakpoint. If it does not find the symbol, it generates an error message and returns to the command line without setting a breakpoint.

If `kadb` fails to find the module on the list of currently loaded modules, it does not resolve the `location`. Instead, it sends a message to the user and sets a deferred breakpoint.

When the specified module is loaded, `kadb` tries to resolve the location. If the location can be resolved, the deferred breakpoint is converted to a regular breakpoint. If `kadb` cannot resolve the location, a message is sent to the user, and `kadb` halts execution. In this case, `kadb` does not convert the deferred breakpoint to a regular breakpoint; it removes it from the breakpoint table. The user may then re-enter a correct breakpoint. Strict scoping is enforced, so `kadb` does not look at any other module than the one specified with the location.

The output from the `$b` command indicates whether the breakpoint is of type "deferred" (`defr`) or is another type.

**FILES**

```
/platform/platform-name/kadb
primary debugger path
```

kadb(1M)

/platform/*hardware-class-name*/kadb  
alternative debugger path for some platforms

/platform/*platform-name*/kernel/unix  
primary default 32-bit kernel

/platform/*hardware-class-name*/kernel/unix  
alternative default 32-bit kernel for some platforms

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcar         |

**SEE ALSO** `adb(1)`, `more(1)`, `uname(1)`, `boot(1M)`, `kernel(1M)`, `attributes(5)`, `kb(7M)`

**SPARC Only** `kbd(1)`, `monitor(1M)`, `obpsym(1M)`

**DIAGNOSTICS** When there is no current command or format, `kadb` comments about syntax errors, abnormal termination of commands, and the like.

**SPARC Only** On a SPARC based system, `kadb` cannot reliably single-step over instructions which change the processor status register.

**NOTES** *platform-name* can be found using the `-i` option of `uname(1)`. *hardware-class-name* can be found using the `-m` option of `uname(1)`.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | kdmconfig – configure or unconfigure keyboard, display, and mouse options for OpenWindows and internationalization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>kdmconfig</b><br><b>kdmconfig</b> [-fv] [-s <i>hostname</i> ] -c   -t   -u   -d <i>filename</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>kdmconfig</code> program configures or unconfigures the <code>/etc/openwin/server/etc/OWconfig</code> file with the keyboard, display, and mouse information relevant to a client's machine on IA based systems for Solaris software. <code>kdmconfig</code> can also be used to set up the <code>display</code>, <code>pointer</code>, and <code>keyboard</code> entries in the <code>bootparams(4)</code> database on a server machine or the <code>monitor</code>, <code>keyboard</code>, <code>display</code>, and <code>pointer</code> keywords in a <code>sysidcfg(4)</code> file. <code>kdmconfig</code> can only be run by the super-user. Upon completion of device selection, <code>kdmconfig</code> prompts the user to test the configuration, which is done by running the window system.</p> <p>The <code>kdmconfig</code> program is normally run during installation and upon reboot, but it can also be run from the command line after the system has been installed. When configuring a client during an initial installation or a reconfigure reboot, the <code>sysidconfig(1M)</code> program will invoke <code>kdmconfig</code> with the <code>-c</code> option, and when the user executes the <code>sys-unconfig(1M)</code> program, <code>kdmconfig</code> will be executed with the <code>-u</code> option. Similarly, when you run <code>kdmconfig</code> from the command line, use the <code>-u</code> option to unconfigure the existing OpenWindows configuration. You can then rerun <code>kdmconfig</code> with the <code>-cf</code> options to create a new OpenWindows configuration. To edit the existing configuration, run <code>kdmconfig</code> from the command line without options. After each reboot, <code>kdmconfig</code> will be invoked by the system with the <code>-t</code> (test mode) option to ensure autoconfiguration capability and identify possible conflicts between the current configuration and the one recorded in the <code>OWconfig</code> file.</p> |
| <b>OPTIONS</b>     | <p>The valid options are:</p> <p><code>-c</code> Run the program in the configuration mode. This mode is used to create or update the <code>OWconfig</code> file. When invoked in this way, <code>kdmconfig</code> first looks for the relevant configuration information in the <code>bootparams(4)</code> databases. It also takes into account the information returned from device probes, unless the <code>-s</code> option is also used. The <code>bootparams(4)</code> databases available to the client are all of the <code>/etc/bootparams</code> files on servers on the same subnet as the client, provided the server machine is running the <code>bootparamd(1M)</code> daemon. <code>kdmconfig</code> is invoked with the <code>-c</code> option when called by <code>sysidconfig(1M)</code></p> <p><code>-d filename</code> Set up a <code>sysidcfg(4)</code> file. This option displays the same screens as the <code>-c</code> option, but the information you specify is saved as <code>sysidcfg(4)</code> keywords (<code>monitor</code>, <code>keyboard</code>, <code>display</code>, and <code>pointer</code>). This enables you to use a <code>sysidcfg(4)</code> file to preconfigure a system's device information and bypass <code>kdmconfig</code> during an installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## kdmconfig(1M)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <p><i>filename</i> is the <code>sysidcfg(4)</code> file that is created, and it is created in the directory where <code>kdmconfig</code> is being run unless a path is specified. If <i>filename</i> already exists in the specified directory, the keywords are appended to the existing file.</p>                                                                                                                                                                                                                                                                                                           |
| <code>-f</code>          | Force screens mode. When this option is invoked, no network probing will be performed. This is helpful when debugging the client's configuration environment. Note that the <code>-s</code> option implies the use of <code>-f</code> , bypassing network probing when setting up a server.                                                                                                                                                                                                                                                                                                                   |
| <code>-s hostname</code> | Set up the <code>bootparams(4)</code> database on this machine for the specified client. This option presents the same screens as it does when run on a client, but instead writes the resulting information to the <code>/etc/bootparams</code> file. Also, <code>-s</code> implies the use of the <code>-f</code> option. That is, the program will always present the screens to the user when invoked this way. This option will reconfigure the <code>nsswitch.conf(4)</code> file to look for a <code>bootparams(4)</code> database on a local server. This option is only available to the super-user. |
| <code>-t</code>          | Run the program in test mode. In this mode, <code>kdmconfig</code> will use device probe information to determine whether the <code>OWconfig</code> file contains complete and up-to-date information about the keyboard, display, and mouse. If the information is accurate, <code>kdmconfig</code> will exit silently. Otherwise, <code>kdmconfig</code> will prompt for the super-user password and proceed to a normal editing session (as though it had been run without options).                                                                                                                       |
| <code>-u</code>          | Unconfigure the system, returning it to an "out-of-the-box" state. In this state, the factory default keyboard, mouse, and display are selected as a result of removing the device configuration entries from the <code>/etc/openwin/server/etc/OWconfig</code> file. This may result in an unusable configuration for the display server.                                                                                                                                                                                                                                                                    |
| <code>-v</code>          | Enable verbose mode. Normally, <code>kdmconfig</code> will not produce any output. This option is helpful for debugging, as it records the different actions taken by <code>kdmconfig</code> on <code>stderr</code> .                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>No Options</b>        | Run without options, <code>kdmconfig</code> is used to edit the current configuration. <code>kdmconfig</code> uses the information from the <code>OWconfig</code> file in addition to information obtained from the <code>bootparams(4)</code> file and from device probes. In other respects, it is similar to using the <code>-c</code> option of <code>kdmconfig</code> .                                                                                                                                                                                                                                  |
| <b>FILES</b>             | <p><code>/etc/openwin/server/etc/OWconfig</code><br/>OpenWindows configuration file</p> <p><code>/etc/bootparams</code><br/>contains list of clients that diskless clients use for booting</p> <p><code>/etc/nsswitch.conf</code><br/>name service configuration file</p>                                                                                                                                                                                                                                                                                                                                     |

kdmconfig(1M)

**IA Only** /dev/openprom installed devices and properties

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Architecture   | IA              |
| Availability   | SUNWos86r       |

**SEE ALSO** `bootparamd(1M)`, `sys-unconfig(1M)`, `sysidconfig(1M)`, `bootparams(4)`, `nsswitch.conf(4)`, `sysidcfg(4)`, `attributes(5)`

kerbd(1M)

**NAME** kerbd – generates and validates Kerberos tickets for kernel RPC

**SYNOPSIS** /usr/sbin/kerbd [-dg]

**DESCRIPTION** kerbd is the usermode daemon which interfaces between kernel RPC and the Kerberos key distribution center (KDC) for the purposes of generating and validating Kerberos authentication tickets. In addition, kerbd maps Kerberos user names into local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. kerbd is automatically started when the system enters the multi-user state.

**OPTIONS**

- d Run in debug mode. kerbd will output various information about Kerberos tickets being processed.
- g Do not initialize the grouplist in the user credential when mapped from Kerberos' principal name. If this option is selected, only each user's group from the passwd entry will be included in mapped credentials.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| NAME        | kernel – UNIX system executable file containing basic operating system services                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| SYNOPSIS    | <b>kernel-name</b> [-afsrvx]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DESCRIPTION | <p>The operating system image, or kernel, is the collection of software made up of the core image files (<code>unix</code> and <code>genunix</code>) all of the modules loaded at any instant in time. The system will not function without a kernel to control it.</p> <p>The kernel is loaded by the <code>boot(1M)</code> command in a machine-specific way. The kernel may be loaded from disk or CD-ROM (<code>diskfull boot</code>) or over the network (<code>diskless boot</code>). In either case, the directories under <code>/platform</code> and <code>/kernel</code> must be readable and must contain executable code which is able to perform the required kernel service. If the <code>-a</code> flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See <code>boot(1M)</code> for more information on loading a specific kernel.</p> <p>If the kernel name is not explicitly specified, then on systems capable of supporting the 64-bit kernel, the boot program will attempt to load the 64-bit kernel in preference to the 32-bit kernel by default. See <code>boot(1m)</code>.</p> <p>The <code>moddir</code> variable contains a colon-separated list of directories that the kernel searches for modules. <code>moddir</code> can be set in the <code>/etc/system</code> file. The minimal default is <code>/platform/platform-name/kernel:/kernel:/usr/kernel</code>, but this default they be overridden by a specific platform. It is common for many systems to override the default path with</p> <p><code>/platform/platform-name/kernel:/platform/hardware-class-name/kernel:/kernel:/usr/kern</code><br/> where <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>, and <i>hardware-class-name</i> can be found using the <code>-m</code> option of <code>uname(1)</code>.</p> <p>The kernel configuration can be controlled using the <code>/etc/system</code> file (see <code>system(4)</code>).</p> <p><code>genunix</code> is the platform-independent component of the base kernel.</p> |
| OPTIONS     | <p><code>-a</code>      Ask the user for configuration information, such as where to find the system file, where to mount <code>root</code>, and even override the name of the kernel itself. Default responses will be contained in square brackets (<code>[]</code>), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged <code>/etc/system</code> file, enter <code>/dev/null</code> at the prompt that asks for the pathname of the system configuration file. See <code>system(4)</code>.</p> <p><code>-f</code>      Causes Autoclient systems to flush and reinitialize the client system's local cache. This flag is ignored for all non-Autoclient systems.</p> <p><code>-r</code>      Reconfiguration boot. The system will probe all attached hardware devices and assign nodes in the file system to represent only those devices actually found. It will also configure the logical namespace in <code>/dev</code> as well as the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## kernel(1M)

physical namespace in `/devices`. See `add_drv(1M)` and `rem_drv(1M)` for additional information about maintaining device drivers.

- s Boot only to init level 's'. See `init(1M)`.
- v Boot with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See `syslogd(1M)`.
- x Do not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

**EXAMPLES** See `boot(1M)` for examples and instructions on how to boot.

### FILES

`/kernel`

Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system. of the core image file.

`/platform/platform-name/kernel`

The platform-specific kernel components.

`/platform/hardware-class-name/kernel`

The kernel components specific to this hardware class.

`/usr/kernel`

Contains kernel components common to all platforms within a particular instruction set.

The `/kernel`, `/platform/platform-name/kernel`, `/platform/hardware-class-name/kernel`, and `/usr/kernel` directories can potentially contain the following subdirectories:

- `drv` Loadable device drivers
- `exec` The modules that execute programs stored in various file formats.
- `fs` File system modules
- `misc` Miscellaneous system-related modules
- `sched` Operating system schedulers
- `strmod` System V STREAMS loadable modules
- `sys` Loadable system calls

### SPARC

Additionally, the subdirectories mentioned in this section may contain `sparcv9` subdirectories that contain 64-bit versions of the same module classes.

`cpu` Processor specific modules

`tod` Time-Of-Day hardware interface modules

### IA

`mach` IA hardware support

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | SUNWcar, SUNWcarx |

**SEE ALSO** `uname(1)`, `isainfo(1)`, `add_drv(1M)`, `boot(1M)`, `init(1M)`, `kadb(1M)`, `rem_drv(1M)`, `savecore(1M)`, `syslogd(1M)`, `system(4)`, `attributes(5)`

**SPARC Only** `monitor(1M)`

**DIAGNOSTICS** The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

**BUGS** Bugs in the kernel often result in kernel panics.

Reconfiguration boot does not currently remove filesystem entries for devices that have been physically removed from the system.

keyserv(1M)

**NAME** keyserv – server for storing private encryption keys

**SYNOPSIS** **keyserv** [-c] [-d] [-D] [-n] [-s *sizespec*]

**DESCRIPTION** *keyserv* is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS and NIS+.

Normally, root’s key is read from the file */etc/.rootkey* when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

**OPTIONS**

- c Do not use disk caches. This option overrides any -s option.
- d Disable the use of default keys for nobody.
- D Run in debugging mode and log all requests to *keyserv*.
- n Root’s secret key is not read from */etc/.rootkey*. Instead, *keyserv* prompts the user for the password to decrypt root’s key stored in the *publickey* database and then stores the decrypted key in */etc/.rootkey* for future use. This option is useful if the */etc/.rootkey* file ever gets out of date or corrupted.
- s *sizespec* Specify the size of the extended Diffie-Hellman common key disk caches. The *sizespec* can be one of the following forms:
  - mechtype=size* *size* is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter *M*, denoting the maximum size in MB.
  - size* This form of *sizespec* applies to all caches.
 See *nisauthconf(1M)* for mechanism types. Note that the *des* mechanism, *AUTH\_DES*, does not use a disk cache.

**FILES** */etc/.rootkey*

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *keylogin(1)*, *keylogout(1)*, *nisauthconf(1M)*, *publickey(4)*, *attributes(5)*

**NOTES** *keyserv* will not start up if the system does not have a secure *rpc* domain configured. Set up the domain name by using the */usr/bin/domainname* command. Usually the */etc/init.d/inetinit* script reads the domain from

keyserv(1M)

/etc/defaultdomain. Invoking the domainname command without arguments tells you if you have a domain set up.

killall(1M)

**NAME** | killall – kill all active processes

**SYNOPSIS** | `/usr/sbin/killall [signal]`

**DESCRIPTION** | killall is used by shutdown(1M) to kill all active processes not directly related to the shutdown procedure.

killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.

killall sends *signal* (see kill(1)) to the active processes. If no *signal* is specified, a default of 15 is used.

The killall command can be run only by the super-user.

**ATTRIBUTES** | See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | kill(1), ps(1), fuser(1M), shutdown(1M), signal(3C), attributes(5)

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |

| <b>NAME</b>                     | kstat – display kernel statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |
| <b>SYNOPSIS</b>                 | <pre><b>kstat</b> [-lpq] [-T u   d] [-c <i>class</i>] [-m <i>module</i>] [-i <i>instance</i>] [-n <i>name</i>]         [-s <i>statistic</i>] [interval [count]]  <b>kstat</b> [-lpq] [-T u   d] [-c <i>class</i>] [<i>module:instance:name:statistic...</i>]         [interval [count]]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |
| <b>DESCRIPTION</b>              | <p>The <code>kstat</code> utility examines the available kernel statistics, or <code>kstats</code>, on the system and reports those statistics which match the criteria specified on the command line. Each matching statistic is printed with its module, instance, and name fields, as well as its actual value.</p> <p>Kernel statistics may be published by various kernel subsystems, such as drivers or loadable modules; each <code>kstat</code> has a module field that denotes its publisher. Since each module may have countable entities (such as multiple disks associated with the <code>sd(7D)</code> driver) for which it wishes to report statistics, the <code>kstat</code> also has an instance field to index the statistics for each entity; <code>kstat</code> instances are numbered starting from zero. Finally, the <code>kstat</code> is given a name unique within its module.</p> <p>Each <code>kstat</code> may be a special <code>kstat</code> type, an array of name-value pairs, or raw data. In the name-value case, each reported value is given a label, which we refer to as the statistic. Known raw and special <code>kstats</code> are given statistic labels for each of their values by <code>kstat</code>; thus, all published values can be referenced as <code>module:instance:name:statistic</code>.</p> <p>When invoked without any module operands or options, <code>kstat</code> will match all defined statistics on the system. Example invocations are provided below. All times are displayed as fractional seconds since system boot.</p>        |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |
| <b>OPTIONS</b>                  | <p>The tests specified by the following options are logically ANDed, and all matching <code>kstats</code> will be selected. A regular expression containing shell meta-characters must be protected from the shell by enclosing it with the appropriate quotes.</p> <p>The argument for the <code>-c</code>, <code>-i</code>, <code>-m</code>, <code>-n</code>, and <code>-s</code> options may be specified as a shell glob pattern, or a Perl regular expression enclosed in <code>'\'</code> characters.</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>-c <i>class</i></code></td> <td>Display only <code>kstats</code> that match the specified class.</td> </tr> <tr> <td><code>-i <i>instance</i></code></td> <td>Display only <code>kstats</code> that match the specified instance.</td> </tr> <tr> <td><code>-l</code></td> <td>List matching <code>kstat</code> names without displaying values.</td> </tr> <tr> <td><code>-m <i>module</i></code></td> <td>Display only <code>kstats</code> that match the specified module.</td> </tr> <tr> <td><code>-n <i>name</i></code></td> <td>Display only <code>kstats</code> that match the specified name.</td> </tr> <tr> <td><code>-p</code></td> <td>Display output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format.</td> </tr> <tr> <td><code>-q</code></td> <td>Display no output, but return appropriate exit status for matches against given criteria.</td> </tr> </table> | <code>-c <i>class</i></code> | Display only <code>kstats</code> that match the specified class. | <code>-i <i>instance</i></code> | Display only <code>kstats</code> that match the specified instance. | <code>-l</code> | List matching <code>kstat</code> names without displaying values. | <code>-m <i>module</i></code> | Display only <code>kstats</code> that match the specified module. | <code>-n <i>name</i></code> | Display only <code>kstats</code> that match the specified name. | <code>-p</code> | Display output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format. | <code>-q</code> | Display no output, but return appropriate exit status for matches against given criteria. |
| <code>-c <i>class</i></code>    | Display only <code>kstats</code> that match the specified class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |

| <code>-n <i>name</i></code>     | Display only <code>kstats</code> that match the specified name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |
| <code>-p</code>                 | Display output in parseable format. All example output in this document is given in this format. If this option is not specified, <code>kstat</code> produces output in a human-readable, table format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |
| <code>-q</code>                 | Display no output, but return appropriate exit status for matches against given criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                              |                                                                  |                                 |                                                                     |                 |                                                                   |                               |                                                                   |                             |                                                                 |                 |                                                                                                                                                                                                         |                 |                                                                                           |

## kstat(1M)

`-s statistic` Display only kstats that match the specified statistic.

`-T d | u` Display a time stamp before each statistics block, either in `ctime(3C)` format ('d') or as an alphanumeric representation of the value returned by `time(2)` ('u').

**OPERANDS** The following operands are supported:

*module:instance:name:statistic* Alternate method of specifying module, instance, name, and statistic as described above. Each of the module, instance, name, or statistic specifiers may be a shell glob pattern or a Perl regular expression enclosed by '' characters. It is possible to use both specifier types within a single operand. Leaving a specifier empty is equivalent to using the '\*' glob pattern for that specifier.

*interval* The number of seconds between reports.

*count* The number of reports to be printed.

**EXAMPLES** In the following examples, all the command lines in a block produce the same output, as shown immediately below. The exact statistics and values will of course vary from machine to machine.

### EXAMPLE 1

```
$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
$ kstat -p -s 'avenrun*'
$ kstat -p 'unix:0:system_misc:avenrun*'
$ kstat -p '>:::avenrun*'
$ kstat -p '>:::^avenrun_\d+min$/'
```

```
unix:0:system_misc:avenrun_15min 3
unix:0:system_misc:avenrun_1min 4
unix:0:system_misc:avenrun_5min 2
```

### EXAMPLE 2

```
$ kstat -p -m cpu_stat -s 'intr*'
$ kstat -p cpu_stat::~/^intr/
```

```
cpu_stat:0:cpu_stat0:intr 29682330
cpu_stat:0:cpu_stat0:intrblk 87
cpu_stat:0:cpu_stat0:intrthread 15054222
cpu_stat:1:cpu_stat1:intr 426073
cpu_stat:1:cpu_stat1:intrblk 51
cpu_stat:1:cpu_stat1:intrthread 289668
cpu_stat:2:cpu_stat2:intr 134160
cpu_stat:2:cpu_stat2:intrblk 0
cpu_stat:2:cpu_stat2:intrthread 131
cpu_stat:3:cpu_stat3:intr 196566
```

**EXAMPLE 2** (Continued)

```
cpu_stat:3:cpu_stat3:intrblk 30
cpu_stat:3:cpu_stat3:intrthread 59626
```

**EXAMPLE 3**

```
$ kstat -p :::state '::::avenrun*'
$ kstat -p :::state :::^avenrun/

cpu_info:0:cpu_info0:state on-line
cpu_info:1:cpu_info1:state on-line
cpu_info:2:cpu_info2:state on-line
cpu_info:3:cpu_info3:state on-line
unix:0:system_misc:avenrun_15min 4
unix:0:system_misc:avenrun_1min 10
unix:0:system_misc:avenrun_5min 3
```

**EXAMPLE 4**

```
$ kstat -p 'unix:0:system_misc:avenrun*' 1 3
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

**EXAMPLE 5**

```
$ kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2
Thu Jul 22 19:39:50 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11

Thu Jul 22 19:39:55 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11
```

**EXAMPLE 6**

```
$ kstat -p -T u 'unix:0:system_misc:avenrun*'
932668656
unix:0:system_misc:avenrun_15min 14
unix:0:system_misc:avenrun_1min 5
unix:0:system_misc:avenrun_5min 18
```

kstat(1M)

**EXAMPLE 6**     *(Continued)*

**EXIT STATUS**    The following exit values are returned:

- 0            One or more statistics were matched.
- 1            No statistics were matched.
- 2            Invalid command line options were specified.
- 3            A fatal error occurred.

**FILES**        /dev/kstat     kernel statistics driver

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**     `sh(1)`, `time(2)`, `ctime(3C)`, `gmatch(3GEN)`, `kstat(3KSTAT)`, `attributes(5)`,  
`kstat(7D)`, `sd(7D)`, `kstat(9S)`

**NOTES**        If the pattern argument contains glob or Perl RE meta-characters which are also shell meta-characters, it will be necessary to enclose the pattern with appropriate shell quotes.

**NAME** kttkt\_warnd – Kerberos warning daemon

**SYNOPSIS** /usr/lib/krb5/kttkt\_warnd

**DESCRIPTION** kttkt\_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire. It is invoked by inetd when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the kinit command. kttkt\_warnd can be configured through the /etc/krb5/warn.conf file on the client.

**FILES** /etc/krb5/warn.conf                      Kerberos warning configuration file

**SEE ALSO** inetd(1M), warn.conf(4), SEAM(5)

labelit(1M)

**NAME** labelit – list or provide labels for file systems

**SYNOPSIS** **labelit** [-F *FSType*] [-V] *special* [*operands*]

**DESCRIPTION** The labelit utility is used to write or display labels on unmounted disk file systems.

**OPTIONS** The following options are supported:

-F *FSType* Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by matching the *special* with an entry in the table. If no matching entry is found, the default file system type specified in /etc/default/fs will be used.

-V Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a /etc/vfstab lookup is included in the output. The command is not executed.

**OPERANDS** The following operands are supported. If no operands are specified, labelit will display the value of the labels.

*special* The disk partition (for example, /dev/rdisk/c0t3d0s6). The device may not be on a remote machine.

*operands* *FSType*-specific operands. Consult the manual page of the *FSType*-specific labelit command for detailed descriptions.

**USAGE** See largefile(5) for the description of the behavior of labelit when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**EXIT STATUS** The following exit values are returned:

0 Write or display of labels was successful.

non-zero An error occurred.

**FILES** /etc/vfstab list of default parameters for each file system

/etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example:

LOCAL=ufs  
LOCAL The default partition for a command if no *FSType* is specified.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

labelit(1M)

**SEE ALSO** volcopy(1M), vfstab(4), attributes(5), largefile(5) Manual pages for the *FSType*-specific modules of labelit

**NOTES** This utility may not be supported for all *FSTypes*.

## labelit\_hfs(1M)

| <b>NAME</b>        | labelit_hfs – provide and print labels for hfs file systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/labelit -F hfs [generic_options] [-o specific_options] special</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).</p> <p><i>generic_options</i> are options supported by the generic labelit command.</p> <p>If no <i>specific_options</i> are specified, labelit prints the current value of all label fields.</p> <p>The <i>special</i> name should be the physical disk section (for example, /dev/dsk/c0d0s6).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-o Use one or more of the following <i>name=value</i> pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, “d-characters” below refers to the characters ‘A’ through ‘Z’, the digits ‘0’ through ‘9’, and the ‘_’ (underscore) character. “a-characters” below refers to ‘A’ through ‘Z’, ‘0’ through ‘9’, space, and the following characters: !"%&amp;'()*+,-./:;&lt;=&gt;?_.</p> <p>absfile= Abstract file identifier, d-characters, 37 characters maximum.</p> <p>applid= Application identifier, d-characters, 128 characters maximum.</p> <p>bibfile= Bibliographic file identifier, d-characters, 37 characters maximum.</p> <p>copyfile= Copyright file identifier, d-characters, 128 maximum.</p> <p>prepid= Data preparer identifier, d-characters, 128 maximum.</p> <p>pubid= Publisher identifier, d-characters, 128 maximum.</p> <p>sysid= System identifier, a-characters, 32 maximum.</p> <p>volid= Volume identifier, d-characters, 32 maximum.</p> <p>volsetid= Volume set identifier, d-characters, 128 maximum.</p> |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>labelit</b> -F udfs [ <i>generic_options</i> ] <i>special</i> [ <i>fsname volume</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>DESCRIPTION</b> | labelit writes labels on an unmounted disk that contains a universal disk file (udf) system. These labels can be used to identify volumes.                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>OPTIONS</b>     | The following options are supported:<br><br><i>generic_options</i> Specify <i>generic_options</i> supported by the generic labelit command. See labelit(1M) for descriptions of supported options.                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>OPERANDS</b>    | The following operands are supported:<br><br><i>special</i> Specify <i>special</i> as the physical disk slice, for example, /dev/rdisk/c0t0d0s6. The device can not be on a remote machine.<br><br><i>fsname</i> Specify <i>fsname</i> as the mount point, (for example, root, u1, and so forth), of the file system.<br><br><i>volume</i> Specify <i>volume</i> as the physical volume name.<br><br>If <i>fsname</i> and <i>volume</i> are not specified, labelit prints the current values of these labels. |                |                 |              |         |
| <b>EXIT STATUS</b> | The following exit values are returned:<br><br>0                        Successful completion.<br>non-zero                An error occurred.                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |

labelit\_ufs(1M)

**NAME** labelit\_ufs – provide and print labels for ufs file systems

**SYNOPSIS** `labelit -F ufs [generic_options] special [fsname volume]`

**DESCRIPTION** labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as volcopy(1M).

**OPTIONS** The following option is supported:

*generic\_options* options supported by the generic labelit command. See labelit(1M).

**OPERANDS** The following operands are supported:

*special* name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.

*fsname* represents the mount point (for example, root, u1, and so on) of the file system.

*volume* may be used to represent the physical volume name.

If *fsname* and *volume* are not specified, labelit prints the current values of these labels. Both *fsname* and *volume* are limited to six or fewer characters.

**EXIT STATUS** The following exit values are returned:

0 Write or display of labels was successful.

non-zero An error occurred.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>                                | ldap_cachemgr – LDAP daemon to cache server and client information for NIS lookups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>                            | <code>/usr/lib/ldap/ldap_cachemgr [-g] [-l <i>log-file</i>] [-r <i>revalidate-interval</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>                         | <p>The <code>ldap_cachemgr</code> utility is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.</p> <p>The <code>ldap_cachemgr</code> utility provides cacheing for all parameters as specified and used by the ldap naming service clients. The <code>ldap_cachemgr</code> utility uses the cache files (see <code>FILES</code>) as cold start files which are originally created by executing the <code>ldapclient(1M)</code> utility. Updates to the cache files take place dynamically if profiles are used.</p> <p>The <code>ldap_cachemgr</code> utility helps improve the performance of the clients that are using LDAP as the Naming service repository. Although it is not required that the <code>ldap_cachemgr</code> daemon be running in order for LDAP naming requests to be serviced, it is strongly recommended that it be run on all machines. It will not only improve the performance on both clients and the server(s), but will also improves system security by making the credential file readable by superuser only.</p> <p>The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache thru a door call. On startup, <code>ldap_cachemgr</code> initializes the cache from the cache files (see <code>ldapclient(1M)</code>) Thus, the cache survives machine reboots.</p> <p>The <code>ldap_cachemgr</code> daemon is normally started from a system startup script.</p> <p>The <code>ldap_cachemgr</code> utility also acts as its own administration tool. If an instance of <code>ldap_cachemgr</code> is already running, commands are passed transparently to the running version.</p> |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>                             | <p>The following options are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>-g</code></td> <td>Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-l <i>log-file</i></code></td> <td>Cause <code>ldap_cachemgr</code> to use a log file other than the default <code>/var/ldap/cachemgr.log</code>.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-r <i>revalidate-interval</i></code></td> <td>Override the built-in default refresh interval. When the refresh interval expires, the cache files are updated. The default for this value is 600 seconds. This value can be overridden from the server profile (see <code>ldapclient(1M)</code>).</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <code>-g</code> | Print current configuration and statistics to standard output. This is the only option executable without superuser privileges. | <code>-l <i>log-file</i></code> | Cause <code>ldap_cachemgr</code> to use a log file other than the default <code>/var/ldap/cachemgr.log</code> . | <code>-r <i>revalidate-interval</i></code> | Override the built-in default refresh interval. When the refresh interval expires, the cache files are updated. The default for this value is 600 seconds. This value can be overridden from the server profile (see <code>ldapclient(1M)</code> ). |
| <code>-g</code>                            | Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |
| <code>-l <i>log-file</i></code>            | Cause <code>ldap_cachemgr</code> to use a log file other than the default <code>/var/ldap/cachemgr.log</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |
| <code>-r <i>revalidate-interval</i></code> | Override the built-in default refresh interval. When the refresh interval expires, the cache files are updated. The default for this value is 600 seconds. This value can be overridden from the server profile (see <code>ldapclient(1M)</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                 |                                                                                                                                 |                                 |                                                                                                                 |                                            |                                                                                                                                                                                                                                                     |

## ldap\_cachemgr(1M)

**EXAMPLE 1** Stop and restart the ldap\_cachemgr daemon. *(Continued)*

**EXAMPLE 2** Force ldap\_cachemgr to re-read the /var/ldap/ldap\_client\_cache and /var/ldap/ldap\_client\_cred files.

```
example# ps -efl | grep ldap
8 S root 10923 1 0 71 20 ? 318
? 11:01:42 ? 0:00 ./ldap_cachemgr
$
example# kill -HUP 10923
```

**FILES** /var/ldap/ldap\_client\_cache cold start file for the ldap\_cachemgr daemon  
/var/ldap/ldap\_client\_cred credential file as created by ldapclient(1M)

**WARNINGS** The ldap\_cachemgr utility is included in the Solaris 8 release on an uncommitted basis only, and is subject to change or removal in a future minor release.

| <b>NAME</b>        | ldapclient, ldap_gen_profile – initialize LDAP client machine or create an LDIF of an LDAP client profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre> /usr/sbin/ldapclient [-v] -P profile_name [-d domainname] LDAP_server_addr  /usr/sbin/ldapclient -i   -m [-O] [-v] [-a none   simple   cram_md5] [-b baseDN] [-B alternate_search_dn] [-d domainname] [-D Bind_DN] [-e client_TTL] [-o timeout_value] [-p server_preference] [-r follow_referrals] [-w client_password] LDAP_server_addr...  /usr/sbin/ldapclient -l  /usr/sbin/ldapclient -u [-v]  /usr/sbin/ldap_gen_profile -P profile_name [-O] [-a none   simple   cram_md5] [-b baseDN] [-B alternate_search_dn] [-d domainname] [-D Bind_DN] [-e client_TTL] [-o timeout_value] [-p server_preference] [-r follow_referrals] [-w client_password] LDAP_server_addr... </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>ldapclient</code> utility can be used to:</p> <ul style="list-style-type: none"> <li>■ initialize LDAP client machines</li> <li>■ restore the network service environment on LDAP clients</li> <li>■ list the contents of the LDAP client cache in human-readable format.</li> </ul> <p>The <code>ldap_gen_profile</code> utility creates (on the standard output) an LDIF file that can be loaded into an LDAP server to be used as the client profile, which can be downloaded by <code>ldapclient</code>.</p> <p>The synopsis (<code>-P profile_name</code>) is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by <code>LDAP_server_addr</code>. This is simplest method and will provide the default format with all the correct settings for talking to the set of servers. It will also ensure that the <code>ldap_cachemgr(1M)</code> can automatically update the configuration file as it changes.</p> <p>The second synopsis (<code>-i   -m</code>) is used to initialize a LDAP client machine. The <code>-i</code> option is used to convert machines to use LDAP or to change the machine's domain name. It assigns a default value for the required parameters if they are not specified. You must be logged in as superuser on the machine that is to become a LDAP client. The <code>-m</code> option is used to modify the parameters in the cache file. It updates the parameter specified.</p> <p>The <code>-i</code> option in conjunction with <code>-a none</code> option can be used to initialize an unauthenticated LDAP client machine without having to specify a password.</p> <p>If the authentication method such as <code>simple</code> or <code>cram_md5r</code> requires a password and one is not specified with the <code>-w client_password</code> option, the administrator is prompted for the password. If one is not provided, the command will fail.</p> |

## ldapclient(1M)

During the client initialization process, files that are being modified are backed up as *files.orig*. The files that are usually modified during a client initialization are: */etc/defaultdomain*, */etc/nsswitch.conf*, and, if they exist, */var/yp/binding/`domainname`* for a NIS(YP) client or */var/nis/NIS\_COLD\_START* for a NIS+ client, or if the machine is already an LDAP client, */var/ldap/ldap\_client\_cache* and */var/ldap/ldap\_client\_cred*. Note that a file will not be saved if a backup file already exists.

The *-i* option does not set up an LDAP client to resolve hostnames using DNS. Refer to the DNS documentation for information on setting up DNS. See *resolv.conf(4)*.

The third synopsis (*-l*) is used to list the LDAP client cache. The output will be human-readable (cache files are not guaranteed to be human-readable.)

The fourth synopsis (*-u*) is used to uninitialized the network service environment, restoring it to the one in use before *ldapclient -i* was executed. You must be logged in as superuser on the machine that is to be restored. The restoration will succeed only if the machine was initialized with *ldapclient -i* because it uses the backup files created by the *-i* option.

The machine must be rebooted after initializing a machine or restoring the network service.

### OPTIONS

The following options are supported:

*-a none | simple | cram\_md5*

Specify authentication method. Multiple values can be specified, separated by commas. The default value is *none*. If *simple* or *cram\_md5* is specified, a password must be provided (see *-w* below).

*-b baseDN*

Specify search baseDN (for example *dc=eng,dc=acme,dc=com*.) The default is the root naming context on the first server specified.

*-B alternate\_search\_dn*

Override the *baseDN* for LDAP searches for any of the databases defined the */etc/nsswitch.conf* file (see *nsswitch.conf(4)*). To add an alternate *baseDN* for a specific database, the format is: *database:(1st search base),(2nd base),...* For example:

```
hosts: (ou=hosts,dc=finance,dc=acme,dc=com) ,
(ou=hosts,dc=eng,dc=acme,dc=com)
```

To remove an alternate *baseDN* for a database, specify the database without any argument (for example, *hosts:*). The default value for all databases is *NULL*.

*-d domainname*

Specify the domain name (which becomes the *defaultdomain* for the machine). The default is the current domain name.

- D *Bind\_DN*  
Specify the Bind Distinguished Name (for example, `cn=proxyagent,ou=profile,cd=eng,dc=acme,dc=com.`)
- e *client\_TTL*  
Specify the TTL value for the client information. This is only relevant if the machine was initialized with a client profile. Set *client\_TTL* to 0 (zero) if you do not wish for `ldap_cachemgr` to attempt an automatic refresh from the servers. The times are specified with either a zero "0" (for no expiration) or a positive integer and either "d" for days, "h" for hours, "m" for minutes or "s" for seconds. The default is 12h.
- i  
Initialize client.
- l (e11)  
List the contents of the LDAP client cache. The output (sent to standard output) is meant to be easily readable (the direct contents of the cache files might not be easily readable.).
- m  
Modify parameters in the configuration file.
- o *timeout\_value*  
Specify LDAP operation timeout value. The default is the TCP default (usually 3 minutes.)
- O  
Inform the client to contact only the servers on the preferred list (if for instance they are at the wrong end of a WAN). The default is FALSE.
- p *server\_preference*  
Specify the server preference list (for example, `129.100.100.0:8080,129.100.200.1:386.`) The preferred servers can be defined either by the server specific address or the subnet that the server resides. To remove the server preference, specify "" for the `-p` option. The default preference is the local subnet.
- P *profile\_name*  
Specify a profile that is downloaded from the server and sets all the entries automatically. This option also sets an expiration time that `ldap_cachemgr` can use to automatically update the file if needed. The default *profile\_name* is 'default' and is stored in the bind distinguished name. The profile name is also stored in cache file.
- r *follow\_referrals*  
Specify the search referral option, either `followref` or `noref`. The default is `followref`.
- u  
Uninitialize LDAP client. This option is appropriate only if `ldapclient` was used to initialize client.

## ldapclient(1M)

`-v`  
Specify verbose mode.

`-w client_password`  
Specify client password for `simple` and `cram_md5` authentication modes. This option is not required if authentication mode is `none`.

**OPERANDS** The following operands are supported:

`LDAP_server_addr` Server address (for example, 129.100.100.1:389,129.100.200.1.) The port number is optional; if not specified, the default LDAP server port number `'389'` is used.

**EXAMPLES** **EXAMPLE 1** Setup a Client Using the Default Profile Stored on the Server Specified

Setup a client using the default profile stored on the server specified. This should list all the correct values for talking to your domain.

```
example# ldapclient -P default 129.100.100.1
```

**EXAMPLE 2** Setup a Client That Uses Only One Server With Authentication Mode of `none`

```
example# ldapclient -i -a none 129.100.100.1
```

**EXAMPLE 3** Setup a Client That Uses Only One Server With Authentication Mode of `cram_md5`

Setup an LDAP client to use `cram_md5` with client password "secret", with the domain information expiring once a week, with no search dereference, with the domain name "xyz.acme.com", and with the LDAP server running on port number 386 at IP address 129.100.100.1.

```
example# ldapclient -i -a cram_md5 -w secret -d xyz.acme.com. \
-r noref 129.100.100.1:386
```

**EXAMPLE 4** Setup a Client That Uses Two Servers With Authentication Mode of `simple`

Setup an LDAPclient using two servers and with authentication mode of `simple`. The user will be prompted for a client password.

```
example# ldapclient -i 129.100.100.1 129.100.234.15:386
```

**EXAMPLE 5** Setup a Client With Authentication Mode of `none`

Setup an LDAP client with authentication mode of `none` that does not try an encrypt the transport with SSL and talks to only one server.

```
example# ldapclient -i -a none -a 129.140.44.1
```

**EXAMPLE 5** Setup a Client With Authentication Mode of none (Continued)

**EXAMPLE 6** Use `ldap_gen_profile` to Set Only the Base Dn and the Server Addresses

Use `ldap_gen_profile` to set only the Base DN and the server addresses, using all possible default values.

```
example# ldap_gen_profile \
-D cn=proxyagent,ou=profile,cd=eng,dc=acme,dc=com \
129.100.100.1 129.100.234.15:386 > ldif_profile
```

**EXAMPLE 7** Create a Profile That Overrides Every Default Value

```
example# ldap_gen_profile -P eng -a cram_md5 -d ge.co.uk -w test123 \
-b dc=eng,dc=ge-uk,dc=com -B ou=people,dc=lab,dc=ge-uk,dc=com \
-D cn=proxyagent,ou=profile,cd=eng,dc=ge-uk,dc=com -r noref \
-e 1h -O -p 129.100.100.0 -o 30s 129.100.200.1 129.100.100.1 \
204.34.5.6 > ldif_profile
```

**EXIT STATUS** The following exit values are returned:

- 0 Success.
- 1 Unspecified failure.
- 2 The server was unreachable (down, slow, unknown).
- 3 The IP address is a reachable, however there is no LDAP server running at the IP address (and port number) specified.
- 4 The LDAP server contacted did not know about the profile name given.

| <b>SYNOPSIS</b>              | <pre> /usr/sbin/link existing-file new-file /usr/xpg4/bin/link existing-file new-file /usr/sbin/unlink file </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                      |                                                       |              |                                                |                 |                                                    |
| <b>DESCRIPTION</b>           | <p>The <code>link</code> and <code>unlink</code> commands link and unlink files and directories. Only super-users can use these commands.</p> <p>Use <code>link</code> to create a new file that points to an existing file. The <i>existing-file</i> and <i>new-file</i> operands specify the existing file and newly-created files. See <b>OPERANDS</b>.</p> <p><code>link</code> and <code>unlink</code> directly invoke the <code>link(2)</code> and <code>unlink(2)</code> system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the <code>ln(1)</code> command. See <code>ln(1)</code>.</p> <p>While linked files and directories can be removed using <code>unlink</code>, it is safer to use <code>rm(1)</code> and <code>rmdir(1)</code> instead. See <code>rm(1)</code> and <code>rmdir(1)</code>.</p> |                      |                                                       |              |                                                |                 |                                                    |
| <b>/usr/xpg4/bin/link</b>    | If the existing file being hard linked is itself a symbolic link, then the newly created file ( <i>new-file</i> ) will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself ( <i>existing-file</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                                                       |              |                                                |                 |                                                    |
| <b>OPERANDS</b>              | <table border="0"> <tr> <td style="padding-right: 20px;"><i>existing-file</i></td> <td>Specifies the name of the existing file to be linked.</td> </tr> <tr> <td><i>file</i></td> <td>Specifies the name of the file to be unlinked.</td> </tr> <tr> <td><i>new-file</i></td> <td>Specifies the name of newly created (linked) file.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | <i>existing-file</i> | Specifies the name of the existing file to be linked. | <i>file</i>  | Specifies the name of the file to be unlinked. | <i>new-file</i> | Specifies the name of newly created (linked) file. |
| <i>existing-file</i>         | Specifies the name of the existing file to be linked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |                                                       |              |                                                |                 |                                                    |
| <i>file</i>                  | Specifies the name of the file to be unlinked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                      |                                                       |              |                                                |                 |                                                    |
| <i>new-file</i>              | Specifies the name of newly created (linked) file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                      |                                                       |              |                                                |                 |                                                    |

| <b>DESCRIPTION</b> | <p>list_devices lists the allocatable devices in the system according to specified qualifications.</p> <p>The <i>device</i> and all device special files associated with the device are listed. The device argument is optional and if it is not present, all relevant devices are listed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-l [<i>device</i>] List the pathname(s) of the device special files associated with the device that are allocatable to the current process. If <i>device</i> is given, list only the files associated with the specified device.</p> <p>-n [<i>device</i>] List the pathname(s) of device special files associated with the device that are allocatable to the current process but are not currently allocated. If <i>device</i> is given, list only the files associated with that device.</p> <p>-s Silent. Suppress any diagnostic output.</p> <p>-u [<i>device</i>] List the pathname(s) of device special files, associated with the device that are allocated to the owner of the current process. If <i>device</i> is given, list only the files associated with that device.</p> <p>-U <i>uid</i> Use the user ID <i>uid</i> instead of the real user ID of the current process when performing the list_devices operation. Only a user with the solaris.devices.revoke authorization can use this option.</p> |                |                 |              |         |
| <b>DIAGNOSTICS</b> | list_devices returns a nonzero exit status in the event of an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>DESCRIPTION</b>       | <p>The <code>listen</code> process “listens” to a network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any connection-oriented network (more precisely, with any connection-oriented transport provider) that conforms to the Transport Layer Interface (TLI) Specification.</p> <p>The listener internally generates a pathname for the minor device for each connection; it is this pathname that is used in the <code>utmpx</code> entry for a service, if one is created. By default, this pathname is the concatenation of the prefix <code>/dev/netspec</code> with the decimal representation of the minor device number. In either case, the representation of the minor device number will be at least two digits (for example, 05 or 27), or longer when it is necessary to accommodate minor device numbers larger than 99.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SERVER INVOCATION</b> | <p>When a connection indication is received, the listener creates a new transport endpoint and accepts the connection on that endpoint. Before giving the file descriptor for this new connection to the server, any designated STREAMS modules are pushed and the configuration script is executed, (if one exists). This file descriptor is appropriate for use with either TLI (see <code>t_sync(3NSL)</code>) or the sockets interface library.</p> <p>By default, a new instance of the server is invoked for each connection. When the server is invoked, file descriptor 0 refers to the transport endpoint, and is open for reading and writing. File descriptors 1 and 2 are copies of file descriptor 0; no other file descriptors are open. The service is invoked with the user and group IDs of the user name under which the service was registered with the listener, and with the current directory set to the HOME directory of that user.</p> <p>Alternatively, a service may be registered so that the listener will pass connections to a standing server process through a FIFO or a named STREAM, instead of invoking the server anew for each connection. In this case, the connection is passed in the form of a file descriptor that refers to the new transport endpoint. Before the file descriptor is sent to the server, the listener interprets any configuration script registered for that service using <code>doconfig(3NSL)</code>, although <code>doconfig</code> is invoked with both the <code>NORUN</code> and <code>NOASSIGN</code> flags. The server receives the file descriptor for the connection in a <code>strrecvfd</code> structure using an <code>I_RECVFD ioctl(2)</code>.</p> <p>For more details about the listener and its administration, see <code>nlsadmin(1M)</code>.</p> |
| <b>OPTIONS</b>           | <code>-m<i>devstem</i></code> The listener will use <i>devstem</i> as the prefix for the pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

*System Administration Guide, Volume 1*

**NOTES** When passing a connection to a standing server, the user and group IDs contained in the `strrecvfd` structure will be those for the listener (that is, they will both be 0); the user name under which the service was registered with the listener is not reflected in these IDs.

When operating multiple instances of the listener on a single transport provider, there is a potential race condition in the binding of addresses during initialization of the listeners, if any of their services have dynamically assigned addresses. This condition would appear as an inability of the listener to bind a static-address service to its otherwise valid address, and would result from a dynamic-address service having been bound to that address by a different instance of the listener.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>     | llc2_loop – loopback diagnostics to test the driver, adapter and network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b> | <pre> /usr/lib/llc2/llc2_loop2 [-v] ppa /usr/lib/llc2/llc2_loop3 ppa sap frames /usr/lib/llc2/llc2_loop3 ppa type frames /usr/lib/llc2/llc2_loop4 [-v] ppa </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Loop 2</b>   | <p>The loop2 test sends a NULL XID frame to the broadcast (all 1's) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:</p> <pre> Unexpected DLPI primitive x, expected y. where x = 5 and y = 6. From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons: </pre> <ul style="list-style-type: none"> <li>■ The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).</li> <li>■ The SAP (0x04) is already in use (for example, the SNA subsystem is up).</li> </ul> |
| <b>Loop 3</b>   | <p>The loop3 test sends 1,495 byte Unnumbered Information (UI) frames to the NULL (all 0's) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The ppa argument specifies the adapter on which to run the test. The ppa is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see llc2_config(1)). For Token Ring or Ethernet, specify an even sap value from 2 through 254, or, for Ethernet only, any type value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. frames is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.</p>                                                                                                                                                                                                                                                                            |
| <b>Loop 4</b>   | <p>The loop4 test sends a TEST frame (no information field) to the broadcast (all 1's) destination MAC address. The source SAP value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):</p> <pre> -Attaching   -Binding </pre>                                                                                                                                                                                                                                                                                                                                                              |

## llc2\_loop(1M)

| <b>SYNOPSIS</b>    | <code>/usr/sbin/locator [-f   -n]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The locator command sets or queries the state of the system locator if such a device exists.</p> <p>Without options, the locator command reports the current state of the system.</p> <p>The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.</p>                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-f</code>        Turns the locator off.</p> <p><code>-n</code>        Turns the locator on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPERANDS</b>    | The following operands are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the <code>locator</code> Command on a Platform Which Has a System Locator LED</p> <p>When issued on a platform which has a system locator LED, the following command turns the locator on:</p> <pre># locator -n # locator The 'system' locator is on</pre> <p><b>EXAMPLE 2</b> Using the <code>locator</code> Command on a Platform Which Does Not Have a System Locator LED</p> <p>When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.</p> <pre># locator -n 'system' locator not found</pre> |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>1            Invalid command line input.</p> <p>2            The requested operation failed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>SYNOPSIS</b>    | <code>/usr/lib/nfs/lockd [-g <i>graceperiod</i>] [-t <i>timeout</i>] [<i>nthreads</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>lockd</code> utility is part of the NFS lock manager, which supports record locking operations on NFS files. See <code>fcntl(2)</code> and <code>lockf(3C)</code>. The lock manager provides two functions:</p> <ul style="list-style-type: none"> <li>■ it forwards <code>fcntl(2)</code> locking requests for NFS mounted file systems to the lock manager on the NFS server</li> <li>■ it generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.</li> </ul> <p>State information kept by the lock manager about these locking requests can be lost if the <code>lockd</code> is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, <code>statd(1M)</code>, of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends <code>SIGLOST</code> to a process.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-g <i>graceperiod</i></code> Specify the number of seconds that clients have to reclaim locks after the server reboots. The default is 45 seconds.</p> <p><code>-t <i>timeout</i></code> Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 15 seconds.</p> <p><code><i>nthreads</i></code> Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to <code><i>nthreads</i></code> threads created as needed in the kernel. <code><i>nthreads</i></code> should be based on the load expected on this server. If <code><i>nthreads</i></code> is not specified, the maximum number of concurrent threads will default to 20.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |

| <b>DESCRIPTION</b> | <p><code>lockfs</code> is used to change and report the status of file system locks. <code>lockfs</code> reports the lock status and unlocks the file systems that were improperly left locked by an application such as <code>ufsdump(1M)</code>. This could occur if <code>ufsdump(1M)</code> is killed using <code>kill(1)</code>.</p> <p>Using <code>lockfs</code> to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.</p> <p>When invoked with no arguments, <code>lockfs</code> lists the UFS file systems that are locked. If <i>file-system</i> is not specified, and <code>-a</code> is specified, <code>lockfs</code> is run on all mounted, UFS type file systems.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The following options are supported. You must be super-user to use any of the following options, with the exception of <code>-a</code>.</p> <ul style="list-style-type: none"><li>-a Apply command to all mounted, UFS type file systems. <i>file-system</i> is ignored when <code>-a</code> is specified.</li><li>-c <i>string</i> Accept a string that is passed as the comment field. The <code>-c</code> only takes affect when the lock is being set using the <code>-d</code>, <code>-h</code>, <code>-n</code>, <code>-u</code>, or <code>-w</code> options.</li><li>-d delete-lock (dlock) the specified <i>file-system</i>. dlock suspends access that could remove directory entries.</li><li>-e error-lock (elock) the specified <i>file-system</i>. elock blocks all local access to the locked file system and returns <code>EWOLDBLOCK</code> on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by <code>fsck</code>, which is usually done automatically (see <code>mount_ufs(1M)</code>). elocked file systems can be unmounted.</li><li>-f Flush all transactions out of the log and write the transactions to the master file system. This option is valid only if logging has been enabled on the file system.</li><li>-h Hard-lock (hlock) the specified <i>file-system</i>. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.</li><li>-n Name-lock (nlock) the specified <i>file-system</i>. nlock suspends accesses that could change or remove existing directories entries.</li><li>-u Unlock (unlock) the specified <i>file-system</i>. unlock awakens suspended accesses.</li><li>-w Write-lock (wlock) the specified <i>file-system</i>. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.</li></ul> |

**OPERANDS** The following operands are supported.

*file-system* A list of path names separated by white spaces.

**USAGE** See `largefile(5)` for the description of the behavior of `lockfs` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** `lockfs` with the `-a` option.

In the following examples, *filesystem* is the pathname of the mounted-on directory (mount point). Locktype is one of "write," "name," "delete," "hard," or "unlock". When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the `lockfs` output when only the `-a` option is specified.

```
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment |
|------------|----------|---------|
| /          | unlock   |         |
| /var       | unlock   |         |

```
example#
```

**EXAMPLE 2** `lockfs` with the `-w` option.

The following example shows the `lockfs` output when the `-w` option is used to write lock the `/var` file system and the comment string is set using the `-c` option. The `-a` option is then specified on a separate command line.

```
example# /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment                    |
|------------|----------|----------------------------|
| /          | unlock   |                            |
| /var       | write    | lockfs: write lock example |

```
example#
```

**EXAMPLE 3** `lockfs` with the `-u` option.

The following example shows the `lockfs` output when the `-u` option is used to unlock the `/var` file system and the comment string is set using the `-c` option.

## lockfs(1M)

**EXAMPLE 3** lockfs with the -u option. (Continued)

```
example# /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example# /usr/sbin/lockfs /var
```

| Filesystem | Locktype | Comment                |
|------------|----------|------------------------|
| /var       | unlock   | lockfs: unlock example |

example#

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `kill(1)`, `mount_ufs(1M)`, `ufsdump(1M)`, `fs_ufs(4)`, `attributes(5)`, `largefile(5)`

*System Administration Guide, Volume 1*

**DIAGNOSTICS** *file system*: Not owner

You must be root to use this command.

*file system*: Deadlock condition detected/avoided

A file is enabled for accounting or swapping, on *file system*.

*file system*: Device busy

Another process is setting the lock on *file system*.

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>                                         | lockstat – report kernel lock and profiling statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>                                     | <b>lockstat</b> [-ACEHI] [-e <i>event_list</i> ] [-i <i>rate</i> ] [-b   -t   -h   -s <i>depth</i> ]<br>[-n <i>nrecords</i> ] [-l <i>lock</i> [, <i>size</i> ]] [-d <i>duration</i> ] [-f <i>function</i> [, <i>size</i> ]]<br>[-T] [-ckgwWRpP] [-D <i>count</i> ] [-o <i>filename</i> ] <i>command</i> [ <i>args</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b>                                  | <p>The lockstat utility gathers and displays kernel locking and profiling statistics. lockstat allows you to specify which events to watch (for example, “spin on adaptive mutex,” “block on read access to rwlock due to waiting writers,” and so forth) how much data to gather for each event, and how to display the data. By default, lockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.</p> <p>lockstat gathers data until the specified command completes. For example, to gather statistics for a fixed-time interval, use <code>sleep(1)</code> as the command, as follows:</p> <pre>example# lockstat sleep 5</pre> <p>When the <code>-I</code> option is specified, lockstat establishes a per-processor high-level periodic interrupt source to gather profiling data. The interrupt handler simply generates a lockstat event whose “caller” is the interrupted PC (program counter). The profiling event is just like any other lockstat event, so all of the normal lockstat options are applicable.</p> <p>lockstat relies on the lockstat(7D) driver, an exclusive-access device that modifies the running kernel’s text to intercept events of interest. This imposes a small but measurable overhead on all system activity, so access to the lockstat(7D) driver is restricted to super-user by default. The system administrator may relax this restriction by changing the permissions on <code>/dev/lockstat</code>.</p> |
| <b>Event selection options:</b>                     | <p><code>-C</code> Watch contention events.</p> <p><code>-E</code> Watch error events.</p> <p><code>-H</code> Watch hold events.</p> <p><code>-I</code> Watch profiling interrupt events.</p> <p><code>-A</code> Watch all lock events. <code>-A</code> is equivalent to <code>-CEH</code>.</p> <p><code>-e event_list</code> Only watch the specified events. <i>event list</i> is a comma-separated list of events or ranges of events such as 1,4-7,35. Run lockstat with no arguments to get a brief description of all events.</p> <p><code>-i rate</code> Interrupt rate (per second) for <code>-I</code>. The default is 97 Hz, so that profiling doesn’t run in lockstep with the clock interrupt (which runs at 100 Hz).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**EXAMPLE 4** Basic kernel profiling

For basic profiling, we don't care whether the profiling interrupt sampled `foo()+0x4c` or `foo()+0x78`; we care only that it sampled somewhere in `foo()`, so we use `-k`. The CPU and PIL aren't relevant to basic profiling because we are measuring the system as a whole, not a particular CPU or interrupt level, so we use `-W`.

```
example# lockstat -kIW -D 20 ./polltest
```

```
Profiling interrupt: 82 events in 0.424 seconds (194
events/sec)
```

| Count | indv | cuml | rcnt | nsec | Hottest   | CPU+PIL | Caller          |

**EXAMPLE 5** Generated-load profiling

In the example above, 5% of the samples were in `poll()`. This tells us how much time was spent inside `poll()` itself, but tells us nothing about how much work was *generated* by `poll()`; that is, how much time we spent in functions called by `poll()`. To determine that, we use the `-g` option. The example below shows that although `polltest` spends only 5% of its time in `poll()` itself, `poll()`-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (`lockstat_intr()`, `cyclic_fire()`, and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do *not* add up to 100% because they are not independent. If 72% of all stack traces contain both `foo()` and `bar()`, then both `foo()` and `bar()` are 72% load generators.

```
example# lockstat -kgIW -D 20 ./polltest
```

```
Profiling interrupt: 80 events in 0.412 seconds (194 events/sec)
```

lockstat(1M)

**EXAMPLE 6** Gathering lock contention and profiling data for a specific module

In this example we use the `-f` option not to specify a single function, but rather to specify the entire text space of the `sbus` module. We gather both lock contention and profiling statistics so that contention can be correlated with overall load on the module.

```
example# modinfo | grep sbus
24 102a8b6f b8b4 59 1 sbus (SBus (sysio) nexus driver)

example# lockstat -kICE -f 0x102a8b6f,0xb8b4 sleep 10
Adaptive mutex spin: 39 events in 10.042 seconds (4 events/sec)
```

| Count | indv | cuml | rcnt | spin | Lock          | Caller          |
|-------|------|------|------|------|---------------|-----------------|
| 15    | 38%  | 38%  | 1.00 | 2    | 0x30005160528 | sync_stream_buf |

**SEE ALSO** attributes(5), lockstat(7D), mutex(9F), rwlock(9F)

**NOTES** The profiling support provided by `lockstat -I` replaces the old (and undocumented) `/usr/bin/kgmon` and `/dev/profile`.

Tail-call elimination may affect call sites. For example, if `foo() + 0x50` calls `bar()` and the last thing `bar()` does is call `mutex_exit()`, the compiler may arrange for `bar()` to branch to `mutex_exit()` with a return address of `foo() + 0x58`. Thus, the `mutex_exit()` in `bar()` will appear as though it occurred at `foo() + 0x58`.

The PC in the stack frame in which an interrupt occurs may be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the `-I` and `-s` options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The `lockstat` technology is provided on an as-is basis. The format and content of `lockstat` output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>DESCRIPTION</b> | <p>lofiadm administers lofi(7D), the loopback file driver. lofi(7D) allows a file to be associated with a block device. That file can then be accessed through the block device. This is useful when the file contains an image of some filesystem (such as a floppy or CD-ROM image), because the block device can then be used with the normal system utilities for mounting, checking or repairing filesystems. See fsck(1M) and mount(1M).</p> <p>Use lofiadm to add a file as a loopback device, remove such an association, or print information about the current associations.</p>                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-a file [device]</b>      Add <i>file</i> as a block device.</p> <p style="padding-left: 40px;">If <i>device</i> is not specified, an available device is picked.</p> <p style="padding-left: 40px;">If <i>device</i> is specified, lofiadm attempts to assign it to <i>file</i>. <i>device</i> must be available or lofiadm will fail. The ability to specify a device is provided for use in scripts that wish to re-establish a particular set of associations.</p> <p><b>-d file   device</b>      Remove an association by <i>file</i> or <i>device</i> name, if the associated block device is not busy, and de-allocates the block device.</p>                                                                   |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>file</i>                      Print the block device associated with <i>file</i>.</p> <p><i>device</i>                    Print the file name associated with the block device <i>device</i>.</p> <p style="padding-left: 40px;">Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.</p> <p style="padding-left: 40px;">When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.</p> |

## lofiadm(1M)

### EXAMPLES

#### EXAMPLE 1 Mounting an existing CD-ROM image

You should ensure that Solaris understands the image before creating the CD. `lofi` allows you to mount the image and see if it works.

This example mounts an existing CD-ROM image (`sparc.iso`), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the `mkisofs` utility from the Internet.

Use `lofiadm` to attach a block device to it:

```
lofiadm -a /home/mike_s/RH6.0/sparc.iso
/dev/lofi/1
```

`lofiadm` picks the device and prints the device name to the standard output. You can run `lofiadm` again by issuing the following command:

```
lofiadm
Block Device File
/dev/lofi/1 /home/mike_s/RH6.0/sparc.iso
```

Or, you can give it one name and ask for the other, by issuing the following command:

```
lofiadm /dev/lofi/1
/home/mike_s/RH6.0/sparc.iso
```

Use the `mount` command to mount the image:

```
mount -F hsfs -o ro /dev/lofi/1 /mnt
```

Check to ensure that Solaris understands the image:

```
df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 512418 512418 0 100% /mnt
ls /mnt
./ RedHat/ doc/ ls-lR rr_moved/
../ TRANS.TBL dosutils/ ls-lR.gz sbin@
.buildlog bin@ etc@ misc/ tmp/
COPYING boot/ images/ mnt/ usr@
README boot.cat* kernels/ modules/
RPM-PGP-KEY dev@ lib@ proc/
```

Solaris can mount the CD-ROM image, and understand the filenames. The image was created properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

```
umount /mnt
lofiadm -d /dev/lofi/1
lofiadm
Block Device File
```

**EXAMPLE 2** Mounting a floppy image

This is similar to Example 1.

Using `lofi` to help you mount files that contain floppy images is helpful if a floppy disk contains a file that you need, but the machine which you're on doesn't have a floppy drive. It is also helpful if you don't want to take the time to use the `dd` command to copy the image to a floppy.

This is an example of getting to MDB floppy for Solaris x86:

```
lofiadm -a /export/s28/MDB_s28x_wos/latest/boot.3
/dev/lofi/1
mount -F pcfs /dev/lofi/1 /mnt
ls /mnt
./ COMMENT.BAT* RC.D/ SOLARIS.MAP*
../ IDENT* REPLACE.BAT* X/
APPEND.BAT* MAKEDIR.BAT* SOLARIS/
umount /mnt
lofiadm -d /export/s28/MDB_s28x_wos/latest/boot.3
```

**EXAMPLE 3** Making a UFS filesystem on a file

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch filesystem. It can be painful (or annoying) to have to re-partition a disk just for the test suite, but you don't have to. You can `newfs` a file with `lofi`

Create the file:

```
mkfile 35m /export/home/test
```

Attach it to a block device. You also get the character device that `newfs` requires, so `newfs` that:

```
lofiadm -a /export/home/test
/dev/lofi/1
newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
 35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
 32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

Note that `ufs` might not be able to use the entire file. Mount and use the filesystem:

```
mount /dev/lofi/1 /mnt
df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 33455 9 30101 1% /mnt
ls /mnt
./ ../ lost+found/
umount /mnt
lofiadm -d /dev/lofi/1
```

lofiadm(1M)

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `lofiadm`: `LC_CTYPE`, `LC_MESSAGES` and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

|    |                        |
|----|------------------------|
| 0  | Successful completion. |
| >0 | An error occurred.     |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `fsck(1M)`, `mount(1M)`, `mount_ufs(1M)`, `attributes(5)`, `lofi(7D)`

**NOTES** Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the `lofi` file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

Associations are not persistent across reboots. A script can be used to re-establish them if required.

The abilities of `lofiadm`, and who can use them, are controlled by the permissions of `/dev/lofictl`. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As shipped, `/dev/lofictl` is owned by `root`, in group `sys`, and mode `0644`, so all users can do query operations but only `root` can change anything. The should probably only be given to a trusted group.

When mounting a filesystem image, take care to use appropriate mount options. In particular, the `nosuid` mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like `logging` or `forcedirectio` for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, `newfs(1M)` requires one.

The output of `lofiadm` (without arguments) may change in future releases.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | logins – list user and system login information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <code>/usr/bin/logins</code> [-admopstux] [-g <i>group...</i> ] [-l <i>login...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | This command displays information on user and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user or system login, user id number, passwd account field value (user name or other information), primary group name, primary group id, multiple group names, multiple group ids, home directory, login shell, and four password aging parameters. The default information is the following: login id, user id, primary group name, primary group id and the account field value. Output is sorted by user id, system logins, followed by user logins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>Options may be used together. If so, any login that matches any criteria will be displayed.</p> <ul style="list-style-type: none"> <li>-a           Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password will expire.</li> <li>-d           Selects logins with duplicate uids.</li> <li>-m           Displays multiple group membership information.</li> <li>-o           Formats output into one line of colon-separated fields.</li> <li>-p           Selects logins with no passwords.</li> <li>-s           Selects all system logins.</li> <li>-t           Sorts output by login instead of by uid.</li> <li>-u           Selects all user logins.</li> <li>-x           Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information consists of password status (PS for password, NP for no password or LK for locked). If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user will receive a password expiration warning message (when logging on) before the password expires.</li> <li>-g <i>group</i>   Selects all users belonging to <i>group</i>, sorted by login. Multiple groups can be specified as a comma-separated list. When the -l and -g options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.</li> </ul> |

## logins(1M)

`-l login` Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in `/etc/nsswitch.conf`, the information can come from the `/etc/passwd` and `/etc/shadow` files and other nameservices. When the `-l` and `-g` options are combined, a user will only be listed once, even if the user belongs to more than one of the selected groups.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>SYNOPSIS</b>                     | <pre>lpadmin -p <i>printer options</i> lpadmin -x <i>dest</i> lpadmin -d [<i>dest</i>] lpadmin -S <i>print-wheel</i> -A <i>alert-type</i> [-W <i>minutes</i>] [-Q <i>requests</i>] lpadmin -M -f <i>form-name</i> [-a [-o <i>filebreak</i>] [-t <i>tray-number</i>]]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>                  | <p>lpadmin configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Adding or Changing a Printer</b> | <p>The first form of the lpadmin command (<code>lpadmin -p <i>printer options</i></code>) is used to configure a new printer or to change the configuration of an existing printer. When creating a new printer, one of three options (<code>-v</code>, <code>-U</code>, or <code>-s</code>) must be supplied. In addition, only one of the following may be supplied: <code>-e</code>, <code>-i</code>, or <code>-m</code>; if none of these three options is supplied, the model standard is used. The <code>-h</code> and <code>-l</code> options are mutually exclusive. Printer and class names may be no longer than 14 characters and must consist entirely of the characters A-Z, a-z, 0-9, dash (-) and underscore (_). If <code>-s</code> is specified, the following options are invalid: <code>-A</code>, <code>-e</code>, <code>-F</code>, <code>-h</code>, <code>-i</code>, <code>-l</code>, <code>-M</code>, <code>-m</code>, <code>-o</code>, <code>-U</code>, <code>-v</code>, and <code>-W</code>.</p> <p>The following <i>printer options</i> may appear in any order.</p> <p><code>-A <i>alert-type</i> [-W <i>minutes</i>]</code></p> <p>The <code>-A</code> option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The <i>alert-types</i> are:</p> <p><code>mail</code><br/>Send the alert message using mail (see mail(1)) to the administrator.</p> <p><code>write</code><br/>Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily.</p> <p><code>quiet</code><br/>Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages will again be sent when another fault occurs with the printer.</p> <p><code>showfault</code><br/>Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is <code>/etc/lp/alerts/printer</code>. It is invoked with three parameters: <i>printer_name</i>, <i>date</i>, <i>file_name</i>. The <i>file_name</i> is the name of a file containing the fault message.</p> |

`none`

Do not send messages; any existing alert definition for the printer will be removed. No alert will be sent when the printer faults until a different alert-type (except `quiet`) is used.

*shell-command*

Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the `mail` and `write` values for this option are equivalent to the values `mail user-name` and `write user-name` respectively, where *user-name* is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list`

Display the type of the alert for the printer fault. No change is made to the alert.

The message sent appears as follows:

```
The printer printer has stopped printing for the reason given below.
Fix the problem and bring the printer back on line.
Printing has stopped, but will be restarted in a few minutes;
issue an enable commant if you want to restart sooner.
```

Unless someone issues the change request:

```
lp -i request-id -P ...to change the page list to print, the current request will be
reprinted from the beginning. The reason(s) it stopped (multiple reasons indicate
reprinted attempts):reason
```

The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If the *printer* is `all`, the alerting defined in this command applies to all existing printers.

If the `-W` option is not used to arrange fault alerting for *printer*, the default procedure is to mail one message to the administrator of *printer* per fault. This is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

`-c class`

Insert *printer* into the specified *class*. *class* will be created if it does not already exist.

- D *comment*  
Save this *comment* for display whenever a user asks for a full description of *printer* (see `lpstat(1)`). The LP print service does not interpret this comment.
- e *printer*  
Copy the interface program of an existing *printer* to be the interface program for *printer*. (Options `-i` and `-m` may not be specified with this option.)
- F *fault-recovery*  
This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of *fault-recovery*:
 

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| continue  | Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.                                                                                                                                                                                                                                                                                                                                                                                  |
| beginning | Start printing the request again from the beginning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| wait      | Disable printing on <i>printer</i> and wait for the administrator or a user to enable printing again.<br><br>During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the <code>-i</code> option of the <code>lp</code> command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning. |
- f `allow:form-list`
- f `deny:form-list`  
Allow or deny the forms in *form-list* to be printed on *printer*. By default no forms are allowed on a new printer.  
  
For each printer, the LP print service keeps two lists of forms: an “allow-list” of forms that may be used with the printer, and a “deny-list” of forms that may not be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.  
  
If the allow-list is not empty, only the forms in the list may be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list may not be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.  
  
The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in

## lpadmin(1M)

disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted. Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted only if the form is currently mounted on the printer. If the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that doesn't have the capabilities needed by the form, the command is rejected.

Note the other use of `-f`, with the `-M` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

`-h`

Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

`-I content-type-list`

Allow *printer* to handle print requests with the content types listed in a *content-type-list*. If the list includes names of more than one type, the names must be separated by commas or blank spaces. (If they are separated by blank spaces, the entire list must be enclosed in double quotes.)

The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters.

| Control Character  | Octal Value | Meaning                                              |
|--------------------|-------------|------------------------------------------------------|
| BACKSPACE          | 10          | move back one character, except at beginning of line |
| TAB                | 11          | move to next tab stop                                |
| LINEFEED (newline) | 12          | move to beginning of next line                       |
| FORMFEED           | 14          | move to beginning of next page                       |
| RETURN             | 15          | move to beginning of current line                    |

To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the *content-type-list*, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the *content-type-list*.

Except for `simple`, each *content-type* name is freely determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

`-i interface`

Establish a new interface program for *printer*. *interface* is the pathname of the new program. (The `-e` and `-m` options may not be specified with this option.)

-l

Indicate that the device associated with *printer* is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option may not be specified with this option.)

`-M -f form-name [-a [-o filebreak]] [-t tray-number]`

Mount the form *form-name* on *printer*. Print requests that need the pre-printed form *form-name* will be printed on *printer*. If more than one printer has the form mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t tray-number` option is specified, printer tray *tray-number* will used.

A form is “unmounted” either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Note the other use of `-f` without the `-M` option above.

`-M -S print-wheel`

Mount the *print-wheel* on *printer*. Print requests that need the *print-wheel* will be printed on *printer*. If more than one printer has *print-wheel* mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request will be printed on the one printer that also meets the other needs of the request.

If the *print-wheel* is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

## lpadmin(1M)

A print wheel is “unmounted” either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Note the other uses of the `-S` option without the `-M` option described below.

### `-m model`

Select *model* interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` may not be specified with this option.)

### `-o option`

The `-o` option defines default printer configuration values given to an interface program. The default may be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).

There are several options which are pre-defined by the system. In addition, any number of key-value pairs may be defined. Each of the predefined and undefined options are described.

### The Predefined Options

The following options are predefined: adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner.

### Adjusting Printer Capabilities

```
length=scaled-decimal-number
width=scaled-decimal-number
cpi=scaled-decimal-number
lpi=scaled-decimal-number
```

The term *scaled-decimal-number* refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of *scaled-decimal-numbers* can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing `c`); numbers that show sizes in inches (marked with a trailing `i`); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the `terminfo` entry for the specified printer type. The defaults may be reset by:

```
lpadmin -p printername -o length=
lpadmin -p printername o width=
lpadmin -p printername o cpi=
lpadmin -p printername o lpi=
```

### Adjusting Printer Port Characteristics

```
stty="' stty-option-list' "
```

The *stty-option-list* is not checked for allowed values, but is passed directly to the stty program by the standard interface program. Any error messages produced by stty when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for stty is:

```
stty="'9600 cs8 -cstopb -parenb ixon
-ixany opost -olcuc onlcr
-ocrnl -onocr
-onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0' "
```

The default may be reset by:

```
lpadmin -p printername -o stty=
```

### Configuring Network Printers

```
dest=string
protocol=string
bsdctrl=string
timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of *dest* is the name of the destination for the network printer; the semantics for value *dest* are dependent on the printer and the configuration. There is no default.

The value of option *protocol* sets the over-the-wire protocol to the printer. The default for option *protocol* is *bsd*. The value of option *bsdctrl* sets the print order of control and data files (BSD protocol only); the default for this option is *control file first*. The value of option *timeout* sets the seed value for backoff time when the printer is busy. The default value for the *timeout* option is 10 seconds. The defaults may be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

### Controlling the Use of the Banner Page

*nobanner*

Allow a user to submit a print request specifying that no banner page be printed.

*banner*

Force a banner page to be printed with every print request, even when a user asks for no banner page. This is the default. Specify *-o nobanner* to allow users

## lpadmin(1M)

to specify `-o nobanner` with the `lp` command. Undefined Options

### *key=value*

Each *key=value* is passed directly to the interface program. Any checking for allowed values is done in the interface program.

Any default values for a given *key=value* option are defined in the interface program. If a default is provided, it may be reset by typing the key without any value:

```
lpadmin -p printername -o key=
```

### `-P` *paper-name*

Specify a paper type list that the printer supports.

### `-r` *class*

Remove *printer* from the specified *class*. If *printer* is the last member of *class*, then *class* will be removed.

### `-S` *list*

Allow either the print wheels or aliases for character sets named in *list* to be used on the printer.

If the printer is a type that takes print wheels, then *list* is a comma or space separated list of print wheel names. (Enclose the list with quotes if it contains blank spaces.) These will be the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels will be considered mountable on the printer, and print requests that ask for a particular print wheel with this printer will be rejected.

If the printer is a type that has selectable character sets, then *list* is a comma or blank separated list of character set name "mappings" or aliases. (Enclose the list with quotes if it contains blank spaces.) Each "mapping" is of the form *known-name=alias*. The *known-name* is a character set number preceded by *cs* (such as *cs3* for character set three) or a character set name from the `terminfo` database entry *csnm*. See `terminfo(4)`. If this option is not used to specify a list, only the names already known from the `terminfo` database or numbers with a prefix of *cs* will be acceptable for the printer. If *list* is the word *none*, any existing print wheel lists or character set aliases will be removed.

Note the other uses of the `-S` with the `-M` option described above.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-S` option can be used.

### `-s` *system-name* [*printer-name*]

Make a remote printer (one that must be accessed through another system) accessible to users on your system. *system-name* is the name of the remote system on which the remote printer is located it. *printer-name* is the name used on the remote

system for that printer. For example, if you want to access *printer1* on *system1* and you want it called *printer2* on your system:

```
-p printer2 -s system1 !printer1
```

**-T *printer-type-list***

Identify the printer as being of one or more *printer-types*. Each *printer-type* is used to extract data from the `terminfo` database; this information is used to initialize the printer before printing each user's request. Some filters may also use a *printer-type* to convert content for the printer. If this option is not used, the default *printer-type* will be unknown; no information will be extracted from `terminfo` so each user request will be printed without first initializing the printer. Also, this option must be used if the following are to work: `-o cpi`, `-o lpi`, `-o width`, and `-o length` options of the `lpadmin` and `lp` commands, and the `-S` and `-f` options of the `lpadmin` command.

If the *printer-type-list* contains more than one type, then the *content-type-list* of the `-I` option must either be specified as `simple`, as empty (`-I ""`), or not specified at all.

**-t *number-of-trays***

Specify the number of trays when creating the printer.

**-u *allow:login-ID-list***

**-u *deny:login-ID-list***

Allow or deny the users in *login-ID-list* access to the printer. By default all users are allowed on a new printer. The *login-ID-list* argument may include any or all of the following constructs:

|                              |                                        |
|------------------------------|----------------------------------------|
| <i>login-ID</i>              | a user on any system                   |
| <i>system-name !login-ID</i> | a user on system <i>system-name</i>    |
| <i>system-name !all</i>      | all users on system <i>system-name</i> |
| <i>all !login-ID</i>         | a user on all systems                  |
| <i>all</i>                   | all users on all systems               |

For each printer, the LP print service keeps two lists of users: an "allow-list" of people allowed to use the printer, and a "deny-list" of people denied access to the printer. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list may use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list may not use the printer. All users can be denied access to the printer by specifying `-u deny:all`. All users may use the printer by specifying `-u allow:all`.

**-U *dial-info***

The **-U** option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, **-U** assigns the “dialing” information *dial-info* to the printer. *dial-info* is used with the `dial` routine to call the printer. Any network connection supported by the Basic Networking Utilities will work. *dial-info* can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if **-U direct** is given, no dialing will take place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, **-U direct** is assumed.

**-v *device***

Associate a *device* with *printer*. *device* is the path name of a file that is writable by `lp`. Note that the same *device* can be associated with more than one printer.

**Removing a Printer Destination**

The **-x *dest*** option removes the destination *dest* (a printer or a class), from the LP print service. If *dest* is a printer and is the only member of a class, then the class will be deleted, too. If *dest* is `all`, all printers and classes are removed. No other *options* are allowed with **-x**.

**Setting/Changing the System Default Destination**

The **-d [*dest*]** option makes *dest* (an existing printer or class) the new system default destination. If *dest* is not supplied, then there is no system default destination. No other *options* are allowed with **-d**.

**Setting an Alert for a Print Wheel****-S *print-wheel* -A *alert-type* [-W *minutes*] [-Q *requests*]**

The **-S *print-wheel*** option is used with the **-A *alert-type*** option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert will be sent for the print wheel. Note the other use of **-A**, with the **-p** option, above.

The *alert-types* are:

|                    |                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mail</code>  | Send the alert message using the <code>mail</code> command to the administrator.                                                                                                                                                                                                                                                                           |
| <code>write</code> | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.                                                                                                                                                       |
| <code>quiet</code> | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the <i>print-wheel</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <b>-Q</b> option. |
| <code>none</code>  | Do not send messages until the <b>-A</b> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).                                                                                                                                                                                                                        |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>shell-command</i> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail user-name</code> and <code>write user-name</code> respectively, where <i>user-name</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another user ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |
| <code>list</code>    | Display the type of the alert for the print wheel on standard output. No change is made to the alert.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

The message sent appears as follows:

```
The print wheel print-wheel needs to be mounted on the printer(s):
printer (integer1requests) integer2 print requests await this print wheel.
```

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the printer list is the total number of requests awaiting the print wheel. It will be less than the sum of the other numbers if some requests can be handled by more than one printer.

If the *print-wheel* is `all`, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the `-W` option is not given, the default procedure is that only one message will be sent per need to mount the print wheel. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert will be sent at intervals specified by *minutes*.

If the `-Q` option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the print wheel are waiting. If the `-Q` option is not given, or *requests* is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the print wheel when it is not mounted.

**EXIT STATUS** The following exit values are returned:

|          |                        |
|----------|------------------------|
| 0        | Successful completion. |
| non-zero | An error occurred.     |

| <b>NAME</b>                        | lpfilter – administer filters used with the LP print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>                    | <code>/usr/sbin/lpfilter -f filter-name { -   -i   -l   -x   -F pathname }</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b>                 | The <code>lpfilter</code> command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>                     | <p>Arguments consist of the <code>-f filter-name</code> option and exactly one of the arguments appearing within braces ( { } ) in the <b>SYNOPSIS</b>.</p> <p><code>-f filter-name</code> Specifies the <i>filter-name</i> of the filter to be added, changed, reset, deleted, or listed. The filter name <code>all</code> is a special filter name defined below. The <code>-f</code> option is required.</p> <p><code>-</code> Adds or changes a filter as specified from standard input. The format of the input is specified below. If <code>-f all</code> is specified with the <code>-</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-F pathname</code> Adds or changes a filter as specified by the contents of the file <i>pathname</i>. The format of the file's contents is specified below. If <code>-f all</code> is specified with the <code>-F</code> option, the specified change is made to all existing filters. This is not useful.</p> <p><code>-i</code> Resets a filter to its default settings. Using <code>-f all</code> with the <code>-i</code> option restores all filters for which predefined settings are available to their original settings.</p> <p><code>-x</code> Deletes a filter. Using <code>-f all</code> with the <code>-x</code> option results in all filters being deleted.</p> <p><code>-l</code> Lists a filter description. Using <code>-f all</code> with the <code>-l</code> option produces a list of all filters.</p> |
| <b>Adding or Changing a Filter</b> | <p>The filter named in the <code>-f</code> option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.</p> <p>When <code>-</code> is specified, standard input supplies the filter description. When <code>-F</code> is specified, the file <i>pathname</i> supplies the filter description. One of these two options must be specified to add or change a filter.</p> <p>When an existing filter is changed with the <code>-F</code> or <code>-</code> option, lines in the filter description that are not specified in the new information are not changed. When a new filter is added with this command, unspecified lines receive default values. See below.</p> <p>Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:</p> <ul style="list-style-type: none"> <li>■ The content type of the request (specified by <code>lp -T</code> or determined implicitly)</li> <li>■ The name of the printer (specified by <code>lp -d</code>)</li> </ul>                                                                                                                                                                                                                                                                                                                                                            |

## lpfilter(1M)

- The printer type (specified by `lpadmin -T`)  
The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.
- The content types acceptable to the printer (specified by `lpadmin -I`)  
The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.
- The modes of printing asked for by the originator of the request (specified by various options to `lp`)

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by `-`) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

Input types: *content-type-list*  
Output types: *content-type-list*  
Printer types: *printer-type-list*  
Printers: *printer-list*  
Filter type: *filter-type*  
Command: *shell-command*  
Options: *template-list*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input types   | This gives the content types that can be accepted by the filter. The default is any. The document content type must be a member of this list for the initial filter in the sequence.                                                                                                                                                                                                                                                                                    |
| Output types  | This gives the content types that the filter can produce from any of the input (content) types. The default is any. The intersection of the output types of this list and the content types acceptable to the printer (from <code>lpadmin -I</code> and <code>lpadmin -T</code> ) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null. |
| Printer types | This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from <code>lpadmin -T</code> ). The default is any.                                                                                                                                                                                                                                                                   |
| Printers      | This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is any.                                                                                                                                                                                                                                                                                         |
| Filter type   | This marks the filter as a <code>slow</code> filter or a <code>fast</code> filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled                                                                                                                                                                                                                                  |

for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value `slow`. That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer.

**Command** This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the *shell-command*; additional options are constructed, based on the characteristics of each print request and on the `Options` field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter.

**Options** This is a comma separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The `-y` and `-P` arguments to the `lp` command cause a filter sequence to be built even if there is no need for a conversion of content types.

In general, each template is of the following form:

*keyword pattern = replacement*

The *keyword* names the characteristic that the template attempts to map into a filter-specific option; each valid *keyword* is listed in the table below.

A *pattern* is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (\*), or a regular expression. If *pattern* matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The *replacement* is what will be used as the option.

Regular expressions are the same as those found on the `regex(5)` manual page. This includes the `\(...\)` and `\n` constructions, which can be used to extract portions of the *pattern* for copying into the *replacement*, and the `&`, which can be used to copy the entire *pattern* into the *replacement*.

The *replacement* can also contain a `*`; it too, is replaced with the entire *pattern*, just like the `&` of `regex(5)`.

The keywords are:

## lpfilter(1M)

| lp Option      | Characteristic            | <i>keyword</i>  | Possible <i>patterns</i>            |
|----------------|---------------------------|-----------------|-------------------------------------|
| -T             | Content type (input)      | INPUT           | content-type                        |
| not applicable | Content type (output)     | OUTPUT          | content-type                        |
| not applicable | Printer type              | TERM            | printer-type                        |
| -d             | Printer name              | PRINTER         | <i>printer-name</i>                 |
| -f, -o cpi=    | Character pitch           | CPI             | integer                             |
| -f, -o lpi=    | Line pitch                | LPI             | integer                             |
| -f, -o length= | Page length               | LENGTH          | integer                             |
| -f, -o width=  | Page width                | WIDTH           | integer                             |
| -P             | Pages to print            | PAGES           | page-list                           |
| -S             | Character set Print wheel | CHARSET CHARSET | character-set-name print-wheel-name |
| -f             | Form name                 | FORM            | form-name                           |
| -y             | Modes                     | MODES           | mode                                |
| -n             | Number of copies          | COPIES          | <i>integer</i>                      |

### Large File Behavior

See `largefile(5)` for the description of the behavior of `lpfilter` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

### EXAMPLES

**EXAMPLE 1** Printing examples.

For example, the template

```
MODES landscape = -1
```

shows that if a print request is submitted with the `-y landscape` option, the filter will be given the option `-1`.

As another example, the template

```
TERM * = -T *
```

shows that the filter will be given the option `-T printer-type` for whichever *printer-type* is associated with a print request using the filter.

As a last example, consider the template

```
MODES prwidth=\(.*\) = -w\1
```

Suppose a user gives the command

```
lp -y prwidth=10
```

**EXAMPLE 1** Printing examples. (Continued)

From the table above, the LP print service determines that the `-y` option is handled by a MODES template. The MODES template here works because the pattern `prwidth=` matches the `prwidth=10` given by the user. The replacement `-w1` causes the LP print service to generate the filter option `-w10`. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See `sh(1)` for a description of a pipeline. If the print service constructs a filter pipeline, the `INPUT` and `OUTPUT` values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.

**Resetting a Filter to Defaults**

If the filter named is one originally delivered with the LP print service, the `-i` option restores the original filter description.

**Deleting a Filter**

The `-x` option is used to delete the filter specified in `filter-name` from the LP filter table.

**Listing a Filter Description**

The `-l` option is used to list the description of the filter named in `filter-name`. If the command is successful, the following message is sent to standard output:

```
Input types: content-type-list
Output types: content-type-list
Printer types: printer-type-list
Printers: printer-list
Filter type: filter-type
Command: shell-command
Options: template-list
```

If the command fails, an error message is sent to standard error.

**EXIT STATUS**

The following exit values are returned:

```
0 Successful completion.
non-zero An error occurred.
```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsu         |

*System Administration Guide, Volume 1*

**NOTES**

If the `lp` command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.

| <b>NAME</b>                      | lpforms – administer forms used with the LP print service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>                  | <b>lpforms</b> -f <i>form-name</i> <i>option</i><br><b>lpforms</b> -f <i>form-name</i> -A <i>alert-type</i> [-P <i>paper-name</i> [-d]] [-Q <i>requests</i> ]<br>[-W <i>minutes</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>               | The <code>lpforms</code> command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its <i>form-name</i> . Users may specify a form when submitting a print request (see <code>lp(1)</code> ). The argument <code>all</code> can be used instead of <i>form-name</i> with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form <i>form-name</i> must be mounted on a printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>                   | The following options are supported:<br><br>-f <i>form-name</i> Specify a form.<br><br>The first form of <code>lpforms</code> requires that one of the following <i>options</i> ( <code>-</code> , <code>-l</code> , <code>-F</code> , <code>-x</code> ) must be used:<br><br>-F <i>pathname</i> To add or change form <i>form-name</i> , as specified by the information in <i>pathname</i> .<br><br>-                    To add or change form <i>form-name</i> , as specified by the information from standard input.<br><br>-l                    To list the attributes of form <i>form-name</i> .<br><br>-x                    To delete form <i>form-name</i> (this option must be used separately; it may not be used with any other option).<br><br>The second form of the <code>lpforms</code> command requires the <code>-A <i>alert-type</i></code> option. The other options are optional.<br><br>-A <i>alert-type</i> Defines an alert to mount the form when there are queued jobs which need it.<br><br>-P <i>paper-name</i> [-d]                Specify the paper name when creating the form. If <code>-d</code> is specified, this paper is the default.<br><br>-Q <i>requests</i> An alert will be sent when a certain number of print requests that need the form are waiting.<br><br>-W <i>minutes</i> An alert will be sent at intervals specified by minutes. |
| <b>Adding or Changing a Form</b> | The <code>-F <i>pathname</i></code> option is used to add a new form, <i>form-name</i> , to the LP print service, or to change the attributes of an existing form. The form description is taken from <i>pathname</i> if the <code>-F</code> option is given, or from the standard input if the <code>-</code> option is used. One of these two options must be used to define or change a form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*pathname* is the path name of a file that contains all or any subset of the following information about the form.

```

Page length: scaled-decimal-number1
Page width: scaled-decimal-number2
Number of pages: integer
Line pitch: scaled-decimal-number3
Character pitch: scaled-decimal-number4
Character set choice: character-set/print-wheel [mandatory]
Ribbon color: ribbon-color
Comment:
comment
Alignment pattern: [content-type]
content

```

The term “scaled-decimal-number” refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The *Comment :* and *comment* items must appear in consecutive order but may appear before the other items, and the *Alignment pattern:* and the *content* items must appear in consecutive order at the end of the file. Also, the *comment* item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a *>* sign. Any leading *>* sign found in the *comment* will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by *form-name* is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the *-u* option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

#### Page length and Page Width

Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages *scaled-decimal-number1* long, and *scaled-decimal-number2* wide using the printer type as a key into the `terminfo(4)` database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.

#### Number of pages

Each time the alignment pattern is printed, the LP print service will attempt to truncate the *content* to a single form by, if possible, passing to each filter the page subset of *1-integer*.

## lpforms(1M)

### Line pitch and Character pitch

Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the `terminfo(4)` database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. *scaled-decimal-number3* is in lines-per-centimeter if a `c` is appended, and lines-per-inch otherwise; similarly, *scaled-decimal-number4* is in characters-per-centimeter if a `c` is appended, and characters-per-inch otherwise. The character pitch can also be given as `elite` (12 characters-per-inch), `pica` (10 characters-per-inch), or `compressed` (as many characters-per-inch as possible).

### Character set choice

When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel *print-wheel* should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If `mandatory` is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.

### Ribbon color

When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be *ribbon-color*.

### Comment

The LP print service will display the *comment* unaltered when a user asks about this form (see `lpstat(1)`).

### Alignment pattern

When mounting this form, an administrator can ask for the *content* to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional *content-type* defines the type of printer for which *content* had been generated. If *content-type* is not given, `simple` is assumed. Note that the *content* is stored as given, and will be readable only by the user `lp`.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

```
Page Length: 66
Page Width: 80
Number of Pages: 1
Line Pitch: 6
Character Pitch: 10
Character Set Choice: any
Ribbon Color: any
```

### Deleting a Form

LP print service" The `-x` option is used to delete the form *form-name* from the LP print service.

**Listing Form Attributes**

The `-l` option is used to list the attributes of the existing form *form-name*. The attributes listed are those described under *Adding and Changing a Form*, above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the `lpstat(1)` command to examine the non-sensitive part of the form description.

**Allowing and Denying Access to a Form**

The `-u` option, followed by the argument `allow:login-ID-list` or `-u deny:login-ID-list` lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the `-F` or `-` option, each of which is described above under *Adding or Changing a Form*.

The *login-ID-list* argument may include any or all of the following constructs:

|                             |                                        |
|-----------------------------|----------------------------------------|
| <i>login-ID</i>             | A user on any system                   |
| <i>system_name!login-ID</i> | A user on system <i>system_name</i>    |
| <i>system_name!all</i>      | All users on system <i>system_name</i> |
| <i>all!login-ID</i>         | A user on all systems                  |
| <i>all</i>                  | All users on all systems               |

The LP print service keeps two lists of users for each form: an “allow-list” of people allowed to use the form, and a “deny-list” of people that may not use the form. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list. (Both forms of the `-u` option can be run together with the `-F` or the `-` option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying `-f deny:all`. All users can be allowed access to a form by specifying `-f allow:all`. (This is the default.)

**Setting an Alert to Mount a Form**

The `-f form-name` option is used with the `-A alert-type` option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the *alert-type* argument specified with the `-A` option. The *alert-types* are:

|                    |                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mail</code>  | Send the alert message using the <code>mail</code> command to the administrator.                                                                                                                     |
| <code>write</code> | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen. |
| <code>quiet</code> | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages                                                                  |

## lpforms(1M)

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | about a known problem. Once the form <i>form-name</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <code>-Q</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>showfault</code> | Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is <code>/etc/lp/alerts/form</code> . It is invoked with three parameters: <i>form_name</i> , <i>date</i> , <i>file_name</i> . <i>file_name</i> is the name of a file containing the form alert message.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>none</code>      | Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>shell-command</i>   | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail login-ID</code> and <code>write login-ID</code> respectively, where <i>login-ID</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another login-ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |
| <code>list</code>      | Display the type of the alert for the form on standard output. No change is made to the alert.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The message sent appears as follows:

```
The form form-name needs to be mounted
on the printer(s):printer (integer1 requests).
integer2 print requests await this form.
Use the ribbon-color ribbon.
Use the print-wheel print wheel, if appropriate.
```

The printers listed are those that the administrator has specified as candidates for this form. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

```
Use any ribbon.
Use any print-wheel.
```

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | <p>If <i>form-name</i> is any, the <i>alert-type</i> defined in this command applies to any form for which an alert has not yet been defined. If <i>form-name</i> is <code>all</code>, the <i>alert-type</i> defined in this command applies to all forms.</p> <p>If the <code>-W <i>minutes</i></code> option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the <code>-W</code> option is equivalent to specifying <code>-W once</code> or <code>-W 0</code>. If <i>minutes</i> is a number greater than 0, an alert will be sent at intervals specified by <i>minutes</i>.</p> <p>If the <code>-Q <i>requests</i></code> option is also given, the alert will be sent when a certain number (specified by the argument <i>requests</i>) of print requests that need the form are waiting. If the <code>-Q</code> option is not given, or the value of <i>requests</i> is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.</p> |
| <b>Listing the Current Alert</b>    | <p>The <code>-f</code> option, followed by the <code>-A</code> option and the argument <i>list</i> is used to list the <i>alert-type</i> that has been defined for the specified form <i>form-name</i>. No change is made to the alert. If <i>form-name</i> is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.</p> <ul style="list-style-type: none"> <li>-                   When <i>requests</i> requests are queued: alert with <i>shell-command</i> every <i>minutes</i> minutes</li> <li>-                   When <i>requests</i> requests are queued: write to <i>user-name</i> every <i>minutes</i> minutes</li> <li>-                   When <i>requests</i> requests are queued: mail to <i>user-name</i> every <i>minutes</i> minutes</li> <li>-                   No alert</li> </ul> <p>The phrase every <i>minutes</i> minutes is replaced with <code>once</code> if <i>minutes</i> (<code>-Wminutes</code>) is 0.</p>                                                               |
| <b>Terminating an Active Alert</b>  | <p>The <code>-A quiet</code> option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold <i>requests</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Removing an Alert Definition</b> | <p>No messages will be sent after the <code>-A none</code> option is used until the <code>-A</code> option is given again with a different <i>alert-type</i>. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Large File Behavior</b>          | <p>See <code>largefile(5)</code> for the description of the behavior of <code>lpforms</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXIT STATUS</b>                  | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0                   Successful completion.</li> <li>non-zero           An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | lpget – get printing configuration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>lpget</b> [-k <i>key</i> ] [ <i>destination...</i>   <i>list</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>The <code>lpget</code> utility reads printing configuration information from the configuration databases in <code>\$HOME/.printers</code>, <code>/etc/printers.conf</code>, <code>printers.conf.byname</code>, <code>printers.org_dir</code>, and FNS printer contexts. This information (called a <i>configuration report</i>) is displayed to the standard output. See <code>printers(4)</code> and <code>printers.conf(4)</code> for information about the printer configuration databases.</p> <p><code>lpget</code> displays a configuration report for all keys for the specified destination or destinations by default. Use the <code>-k</code> option to display a configuration report for specific keys. Use the <code>list</code> operand to display a configuration report for all configured destinations.</p> |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p><code>-k <i>key</i></code>      Displays a configuration report for <i>key</i>. See <code>printers.conf(4)</code> for information about specifying <i>key</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>destination</i>      Displays a configuration report for <i>destination</i>. Destination can be either a printer or a class of printers, (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic, POSIX-style (<code>server:destination</code>), or Federated Naming Service (FNS) (<code>../service/printer/...</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information concerning POSIX.</p> <p><i>list</i>              Displays a configuration report for all configured destinations.</p>                                                                                                                                            |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Displaying a configuration report for the <code>bsdaddr</code> key</p> <p>The following example displays a configuration report for the <code>bsdaddr</code> key for printer <code>catalpa</code>.</p> <pre>example% lpget -k bsdaddr catalpa</pre> <p><b>EXAMPLE 2</b> A configuration report for all keys for all configured destinations</p> <p>The following example displays a configuration report for all keys for all configured destinations.</p> <pre>example% lpget list</pre>                                                                                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                      Successful completion.</p> <p>non-zero              An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

lpget(1M)

**FILES** /etc/printers.conf  
System printer configuration database.

\$HOME/.printers  
User-configurable printer database.

printers.conf.byname  
NIS version of /etc/printers.conf.

printers.org\_dir  
NIS+ version of /etc/printers.conf.

fns.ctx\_dir.domain  
FNS version of /etc/printers.conf.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWpcu         |
| Stability Level | Stable          |

| <b>NAME</b>        | lpmove – move print requests                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>lpmove</b> <i>request- ID destination</i><br><b>lpmove</b> <i>destination1 destination2</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>lpmove</code> command moves print requests queued by <code>lp(1)</code> or <code>lpr(1B)</code> between destinations. Only use <code>lpmove</code> to move jobs on the local system.</p> <p>The first form of <code>lpmove</code> moves specific print requests (<i>request-ID</i>) to a specific (<i>destination</i>).</p> <p>The second form of the <code>lpmove</code> command moves all print requests from one destination (<i>destination1</i>) to another (<i>destination2</i>). This form of <code>lpmove</code> also rejects new print requests for <i>destination1</i>.</p> <p>When moving requests, <code>lpmove</code> does not check the acceptance status of the destination to which the print requests are being moved (see <code>accept(1M)</code>). <code>lpmove</code> does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPERANDS</b>    | <p>The following operands are supported.</p> <p><i>destination</i>            The name of the printer or class of printers (see <code>lpadmin(1M)</code>) to which <code>lpmove</code> moves a <i>specified</i> print request. Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>.../service/printer/...</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names.</p> <p><i>destination1</i>           The name of the destination from which <code>lpmove</code> moves <i>all</i> print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>.../service/printer/...</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><i>destination2</i>           The name of the destination to which <code>lpmove</code> moves all print requests. Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<i>.../service/printer/...</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names.</p> <p><i>request-ID</i>            The specific print request to be moved. Specify <i>request-ID</i> as the identifier associated with a print request as reported by <code>lpstat</code>. See <code>lpstat(1)</code>.</p> |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                        Successful completion.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

lpmove(1M)

non-zero            An error occurred.

| <b>SYNOPSIS</b>    | <b>lpsched</b> [-f <i>num_filters</i> ] [-n <i>num_notifiers</i> ] [-p <i>fd_limit</i> ] [-r <i>reserved_fds</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The lpsched command starts or restarts the LP print service.</p> <p>The lpshut command stops the LP print service. Printers that are restarted using lpsched reprint (in their entirety) print requests that were stopped by lpshut. See lpshut(1M).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-f <i>num_filters</i>                      Specifies the number of concurrent slow filters that may be run on a print server. A default value of 1 is used if none is specified. Depending on server configuration, a value of 1 may cause printers to remain idle while there are jobs queued to them.</p> <p>-n <i>num_notifiers</i>                      Specifies the number of concurrent notification processes that can run on a print server. A default value of 1 is used when none is specified.</p> <p>-p <i>fd_limit</i>                              Specifies the file descriptor resource limit for the lpsched process. A default value of 4096 is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.</p> <p>-r <i>reserved_fds</i>                      Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of 2 is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.</p> |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                                          Successful completion.</p> <p>non-zero                                  An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |

| <b>NAME</b>        | lpset – set printing configuration in /etc/printers.conf or FNS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>lpset</b> [-n system   nisplus   fns] [-x] [-a <i>key=value</i> ] [-d <i>key</i> ]<br><i>destination</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The lpset utility sets printing configuration information in the system configuration databases. Use lpset to create and update printing configuration in /etc/printers.conf, printers.org_dir (NIS+), or Federated Naming System (FNS). See nsswitch.conf(4), printers.conf(4), and fns(5).</p> <p>Only a superuser or a member of Group 14 may execute lpset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>[-n system nisplus fns]</b> Creates or updates the configuration information for the <i>destination</i> entry in /etc/printers.conf, printers.org_dir (NIS+), or FNS printer contexts. system specifies that the information is created or updated in /etc/printers.conf. nisplus specifies that the information is created or updated in the printers.org_dir NIS+ table. fns specifies that the information is written using federated naming context.</p> <p>If -n is not specified, system is the default.</p> <p><b>-x</b> Removes all configuration for the <i>destination</i> entry in /etc/printers.conf, printers.org_dir (NIS+), or FNS.</p> <p><b>-a <i>key=value</i></b> Configures the specified <i>key=value</i> pair for the <i>destination</i> entry in /etc/printers.conf, printers.org_dir, or FNS. See printers.conf(4) for information regarding the specification of <i>key=value</i> pairs.</p> <p><b>-d <i>key</i></b> Deletes the configuration option specified by <i>key</i> for the <i>destination</i> entry in /etc/printers.conf or FNS. See printers.conf(4) for information regarding the specification of <i>key</i> and <i>key=value</i> pairs.</p> |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><b><i>destination</i></b> Specifies the entry in /etc/printers.conf, printers.org_dir, or FNS in which to create or modify information. <i>destination</i> names a printer of class of printers (see lpadmin(1M)). Each entry in printers.conf describes one destination. Specify <i>destination</i> using atomic or Federated Naming Service (FNS) (../service/printer/...) names. POSIX-style destination names are not acceptable. See printers.conf(4) for information regarding the naming conventions for atomic and FNS names, and standards(5) for information regarding POSIX.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**EXAMPLES** **EXAMPLE 1** Removing all existing printing configuration information

The following example removes all existing printing configuration information for destination `dogs` from `/etc/printers.conf`:

```
example% lpset -x dogs
```

**EXAMPLE 2** Setting a key=value pair

The following example sets the `user-equivalence=true` *key=value* pair for destination `tabloid` in FNS context:

```
example% lpset -n fns -a user-equivalence=true tabloid
```

**EXIT STATUS** The following exit values are returned:

```
0 Successful completion.
non-zero An error occurred.
```

**FILES** `/etc/printers.conf`  
System configuration database.

`printer.org_dir (NIS+)`  
NIS+ version of `/etc/printers.conf`.

`fns.ctx_dir.domain`  
FNS version of `/etc/printers.conf`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWpcu         |
| Stability Level | Stable          |

lpshut(1M)

**NAME** lpshut – stop the LP print service

**SYNOPSIS** **lpshut**

**DESCRIPTION** The lpshut command stops the LP print service.

Printers that are printing when lpshut is invoked stop printing. Start or restart printers using lpsched(1M).

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES** /var/spool/lp/\* LP print queue.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsu         |

**SEE ALSO** lp(1), lpstat(1), lpadmin(1M), lpmove(1M), lpsched(1M), attributes(5)

*System Administration Guide, Volume 1*

- NAME** | lpsystem – register remote systems with the print service
- DESCRIPTION** | The `lpsystem` command is obsolete, and could be removed at any time. The print system no longer uses the information generated by `lpsystem`. See `lpadmin(1M)`, `lpusers(1M)` or `printers.conf(4)` for equivalent functionality.
- ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWpcu         |
| Stability Level | Obsolete*       |

\* This command could be removed at any time.

- SEE ALSO** | `lpadmin(1M)`, `lpusers(1M)`, `printers.conf(4)`, `attributes(5)`

## lpusers(1M)

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                 |                      |                                      |                                         |                         |                                        |                      |                       |     |                          |

| <b>DESCRIPTION</b>                   | <p>The <b>lpusers</b> command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.</p> <p>The first form of the command (with -d) sets the system-wide priority default to <i>priority-level</i>, where <i>priority-level</i> is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see <b>lp(1)</b>), the default priority level is used. Initially, the default priority level is 20.</p> <p>The second form of the command (with -q and -u) sets the default highest <i>priority-level</i> ( 0-39 ) that the users in <i>login-ID-list</i> can request when submitting a print request. The <i>login-ID-list</i> argument may include any or all of the following constructs:</p> <table><tr><td><i>login-ID</i></td><td>A user on any system</td></tr><tr><td><i>system_name</i>!<i>login-ID</i></td><td>A user on the system <i>system_name</i></td></tr><tr><td><i>system_name</i>!all</td><td>All users on system <i>system_name</i></td></tr><tr><td>all!<i>login-ID</i></td><td>A user on all systems</td></tr><tr><td>all</td><td>All users on all systems</td></tr></table> <p>Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.</p> <p>The third form of the command (with -u) removes any explicit priority level for the specified users.</p> <p>The fourth form of the command (with -q) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.</p> <p>The last form of the command (with -l) lists the default priority level and the priority limits assigned to users.</p> | <i>login-ID</i> | A user on any system | <i>system_name</i> ! <i>login-ID</i> | A user on the system <i>system_name</i> | <i>system_name</i> !all | All users on system <i>system_name</i> | all! <i>login-ID</i> | A user on all systems | all | All users on all systems |

- l  
List the default priority level and the priority limits assigned to users.
- q *priority-level*  
Set the default highest priority level for all users not explicitly covered.
- q *priority-level* -u *login-ID-list*  
Set the default highest *priority-level* that the users in *login-ID-list* can request when submitting a print request.
- u *login-ID-list*  
Remove any explicit priority level for the specified users.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

| <b>SYNOPSIS</b>    | <code>/usr/sbin/lu</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                    |         |                                                                                                                                                         |      |                                                                                                                                                                                                       |        |                                                                                              |         |                                                                                                                   |        |                                                                                              |      |                                                                                                                |        |                                                                                                          |        |                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>lu</code> program is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lu</code> program is a Forms and Menu Language Interpreter-based user interface. (See <code>fml(1)</code> for a description of the Forms and Menu Language Interpreter.) <code>lu</code> enables you to create and upgrade boot environments (BEs) and perform other administrative tasks on BEs. The <code>lu</code> program performs a subset of the functions provided by the <code>lucreate(1M)</code> and <code>luupgrade(1M)</code> command-line utilities.</p> <p>The <code>lu</code> command accepts no arguments. After invoking <code>lu</code>, you receive a display with the following options:</p> <table><tr><td>Activate</td><td>Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility.</td></tr><tr><td>Cancel</td><td>Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility.</td></tr><tr><td>Compare</td><td>Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility.</td></tr><tr><td>Copy</td><td>Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled.</td></tr><tr><td>Create</td><td>Create a boot environment. Equivalent of the command-line <code>lucreate(1M)</code> utility.</td></tr><tr><td>Current</td><td>Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility.</td></tr><tr><td>Delete</td><td>Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility.</td></tr><tr><td>List</td><td>List the file systems of a boot environment. Equivalent of the command-line <code>lufslist(1M)</code> utility.</td></tr><tr><td>Rename</td><td>Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility.</td></tr><tr><td>Status</td><td>List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility.</td></tr></table> | Activate | Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility. | Cancel | Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility. | Compare | Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility. | Copy | Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled. | Create | Create a boot environment. Equivalent of the command-line <code>lucreate(1M)</code> utility. | Current | Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility. | Delete | Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility. | List | List the file systems of a boot environment. Equivalent of the command-line <code>lufslist(1M)</code> utility. | Rename | Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility. | Status | List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility. |
| Activate           | Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |          |                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                    |         |                                                                                                                                                         |      |                                                                                                                                                                                                       |        |                                                                                              |         |                                                                                                                   |        |                                                                                              |      |                                                                                                                |        |                                                                                                          |        |                                                                                                             |
| Cancel             | Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |          |                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                    |         |                                                                                                                                                         |      |                                                                                                                                                                                                       |        |                                                                                              |         |                                                                                                                   |        |                                                                                              |      |                                                                                                                |        |                                                                                                          |        |                                                                                                             |
| Compare            | Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. | Status             | List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |          |                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                    |         |                                                                                                                                                         |      |                                                                                                                                                                                                       |        |                                                                                              |         |                                                                                                                   |        |                                                                                              |      |                                                                                                                |        |                                                                                                          |        |                                                                                                             |

|                         |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | Upgrade | Upgrade a boot environment or upgrade the OS on an inactive BE. This option enables you to upgrade to a new operating system or install new packages or patches on a specified BE. Equivalent of the command-line <code>luupgrade(1M)</code> utility.                                                                                                                                                                                                                                                                                                                                                                            |
|                         | Flash   | Flash a boot environment. This option enables you to install an operating system on a BE from a flash archive. You can perform the same function with <code>luupgrade(1M)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                         | Help    | Displays help information. There are also context-specific help screens for many of the options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                         | Exit    | Exit <code>lu</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Navigation</b>       |         | You navigate through <code>lu</code> 's various screens using arrow keys and function keys (usually F2 through F9 on the keyboard of a Sun desktop system). Available key functions are displayed at the base of the <code>lu</code> screen. You can use Ctrl-F, plus a number key, to duplicate a function key. For example, press Ctrl-F and the number key 2 to duplicate the F2 key.                                                                                                                                                                                                                                         |
|                         |         | In a screen for a given option, you can press Esc to obtain context-specific help.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Display Issues</b>   |         | When viewing the FMLI interface remotely, such as over a <code>tip</code> line, you might need to set the <code>TERM</code> environment variable to <code>VT220</code> . When using the FMLI interface in a CDE environment use <code>dtterm</code> , rather than <code>xterm</code> , as the value of the <code>TERM</code> variable.                                                                                                                                                                                                                                                                                           |
|                         |         | The <code>lu</code> command supports only single-byte environments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Common Functions</b> |         | Most of the options listed above offer the following functions. These functions are accessible through function keys indicated at the base of the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                         | Choice  | Available to you whenever you have a field that can be filled in. Pressing the Choice function key gives you a popup screen displaying a list of alternatives. For example, for options involving copying or upgrading BEs, you receive a list of available BEs. You can then use arrow and function keys to make a selection from this popup. The choice function is useful because it prevents you from selecting an invalid alternative. In our example, it prevents you from choosing a BE that is not available for a copy or upgrade operation. Such non-availability might occur when a BE is in the midst of an upgrade. |
|                         | Cancel  | Cancel an operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                         | Save    | Proceed with an operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Other Functions</b>  |         | The "Create" option, described above, offers the following functions:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | Split   | Split a file system. For example, you can split a <code>/</code> file system into <code>/</code> , <code>/usr</code> , and <code>/var</code> . To split a file system, you must have disk slices available on which to mount the separated file system(s). If you do not, <code>lu</code> invokes the <code>format(1M)</code> utility, in which you can use the <code>partition</code> option to create a new disk slice.                                                                                                                                                                                                        |

lu(1M)

**Merge** Join one or more file systems with its (or their) parent file system. For example, using a source BE that has separate `/`, `/usr`, and `/var` file systems, you can merge these file systems under `/` on a target BE.

**FILES** `/etc/lutab` list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWluu         |

**SEE ALSO** `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

| <b>NAME</b>        | luactivate – activate a boot environment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/luactivate [-l <i>error_log</i>] [-o <i>outfile</i>] [-s] [<i>BE_name</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>luactivate</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>luactivate</code> command, with no arguments, displays the name of the boot environment (BE) that will be active upon the next reboot of the system. When an argument (a BE) is specified, <code>luactivate</code> activates the specified BE.</p> <p><code>luactivate</code> activates a BE by making the BE's root partition bootable. On an IA machine, this might require that you take steps following the completion of <code>luactivate</code>. If so, <code>luactivate</code> displays the correct steps to take.</p> <p>To successfully activate a BE, that BE must meet the following conditions:</p> <ul style="list-style-type: none"> <li>■ The BE must have a status of "complete," as reported by <code>lustatus(1M)</code>.</li> <li>■ If the BE is not the current BE, you cannot have mounted the partitions of that BE (using <code>lumount(1M)</code> or <code>mount(1M)</code>).</li> <li>■ The BE you want to activate cannot be involved in an <code>lucompare(1M)</code> operation.</li> </ul> <p>After activating a specified BE, <code>luactivate</code> displays the steps to be taken for fallback in case of any problem on the next reboot. Make note of these instructions and follow them exactly, if necessary.</p> <p>The <code>luactivate</code> command requires root privileges.</p> |
| <b>OPTIONS</b>     | <p>The <code>luactivate</code> command has the following options:</p> <p><code>-l <i>error_log</i></code>     Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p><code>-o <i>outfile</i></code>        All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p> <p><code>-s</code>                    Forced synchronization. The first time you boot from a newly created BE, Live Upgrade software synchronizes this BE with the BE that was last active. (This is not necessarily the BE that was the source for the newly created BE.) It does not perform this synchronization after this initial boot, unless you use this option. Use this option with great caution, because you might not be aware or in control of changes that might have occurred in the last active BE.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPERANDS</b>    | <i>BE_name</i> Name of the BE to be activated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                    Successful completion.</p> <p>&gt;0                   An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/lucancel [-l <i>error_log</i>] [-o <i>outfile</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>lucancel</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lucancel</code> command cancels a boot environment (BE) creation or upgrade that was scheduled in the FMLI-based interface, <code>lu(1M)</code>, or the repopulation of a BE, scheduled with <code>lumake(1M)</code>. <code>lucancel</code> does not cancel a job that is active (that is, is in the process of creation or repopulation).</p> <p>The <code>lucancel</code> command requires root privileges.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The <code>lucancel</code> command has the following options:</p> <p><code>-l <i>error_log</i></code>    Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p><code>-o <i>outfile</i></code>        All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p>                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>&gt;0          An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/lutab</code> list of BEs on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |

| <b>NAME</b>        | lucompare – compare boot environments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |               |      |           |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/lucompare [-i <i>infile</i>   -t] [-o <i>outfile</i>] <i>BE_name</i><br/>/usr/sbin/lucompare [-C <i>file</i> [-o <i>outfile</i>]]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |               |      |           |
| <b>DESCRIPTION</b> | <p>The <code>lucompare</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lucompare</code> command compares the contents of the current boot environment (BE) with the contents of another BE. With the <code>-C</code> option, <code>lucompare</code> compares file statistics so that you can determine which files have changed on a BE since a specified time, such as the creation time of a BE. A specified BE must be inactive and in the complete state, as reported by the <code>lustatus(1M)</code> command. Also, a BE cannot have a copy job scheduled, which is also reported by <code>lustatus(1M)</code>. A specified BE cannot have any partitions mounted with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> <p>For each file system defined for a specified BE, <code>lucompare</code> compares all files with the files with the same pathnames in the current BE. The files present in the active BE, but not in the specified BE, and vice-versa, are reported. You also have the option to specify a list of files to be compared.</p> <p>If you specify the <code>-C</code> option, instead of doing an absolute comparison of the current BE with a target BE, <code>lucompare</code> compares the files in a specified BE with the list of files recorded in a file. When a BE is created, <code>lucreate(1M)</code> creates a file named <code>&lt;BE_name&gt;</code> in <code>/etc/lu/compare</code>. You can use the <code>-C</code> option to compare the files in a specified BE to this snapshot in <code>/etc/lu/compare</code> or you can compare the BE to a file previously created with the <code>-o</code> option. Comparing a BE to its own snapshot in <code>/etc/lu/compare</code> enables you to determine which files have changed on the BE since its creation.</p> <p>By default, the output of <code>lucompare</code> is written to <code>stdout</code>. With the <code>-C</code> option, you must use the <code>-o</code> option to specify an output file. The output for <code>lucompare</code> is a list of files that differ in permissions, owner, group, or sum, along with the reason for difference. The output format is shown below:</p> <pre>&gt; active BE<br/>&lt; BE_name<br/>reason<br/>&gt; file_name:owner:group:number_of_links:mode:type: size<br/>  or major_minor number:checksum<br/>&lt; file_name:owner:group:number_of_links:mode:type: size<br/>  or major_minor number:checksum</pre> <p>The above fields are obtained from the <code>stat(2)</code> structure of the file.</p> <p>The <code>type</code> field can be one of the following:</p> <table><tr><td>SYMLINK</td><td>symbolic link</td></tr><tr><td>FIFO</td><td>FIFO file</td></tr></table> | SYMLINK | symbolic link | FIFO | FIFO file |
| SYMLINK            | symbolic link                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |         |               |      |           |
| FIFO               | FIFO file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |               |      |           |

|        |                   |
|--------|-------------------|
| CHRSPC | character special |
| BLKSPC | block special     |
| DIR    | directory         |
| REGFIL | regular file      |
| UNKNOW | unknown file type |

lucompare computes checksums only if the file on the specified BE matches its counterpart on the active BE in all of the fields described above. If the checksums differ, lucompare appends the differing checksums to the entries for the compared files.

The lucompare command requires root privileges.

**OPTIONS** The lucompare command has the following options:

|                         |                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-C file</code>    | Compare file statistics of BE with those recorded in <i>file</i> . <i>file</i> can be the snapshot created at BE creation time, <code>/etc/lu/compare/&lt;BE_name&gt;</code> , or a file previously created with the <code>-o</code> option. You must use the <code>-o</code> option with this option. |
| <code>-i infile</code>  | Compare files listed in <i>infile</i> . The files to be compared should be an absolute filename. If the entry in the file is a directory, then comparison is recursive with respect to the directory. Mutually exclusive of <code>-t</code> .                                                          |
| <code>-o outfile</code> | Send output of differences to <i>outfile</i> . You must use this option if you use <code>-C</code> .                                                                                                                                                                                                   |
| <code>-t</code>         | Compare only nonbinary files. This is achieved by performing a <code>file(1)</code> command on each file in the tree walk and only comparing text files. Mutually exclusive of <code>-i</code> .                                                                                                       |

**OPERANDS** *BE\_name* Name of the BE to which the active BE will be compared. You cannot specify a BE that is involved in another Live Upgrade operation, or specify a BE for which you have mounted partitions (using `lumount(1M)` or `mount(1M)`).

**EXAMPLES** **EXAMPLE 1** Checking Differences Since BE Creation

The following command lists the differences in the BE `s8u5` between its creation time and the present.

```
lucompare -C /etc/lu/compare/:s8u5 -o /var/tmp/compare.out s8u5
```

Note that `/etc/lu/compare/:s8u5` is the file created by `lucreate` upon creation of a BE. The list of differences is sent to `/var/tmp/compare.out`.

## lucompare(1M)

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES** /etc/lutab list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWluu         |

**SEE ALSO** `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslst(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

**NOTES** The `lucompare` command makes no attempt to reconcile any differences it detects between BEs.

| <b>NAME</b>        | lucreate – create a new boot environment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre><b>lucreate</b> [-c <i>BE_name</i>] [-C ( <i>boot_device</i>   - )] -n <i>BE_name</i> [-l <i>error_log</i>] [-o <i>outfile</i>] [-s ( -   <i>source_BE_name</i> )] [ [-M <i>slice_list</i>]   [-m <i>mountpoint:device:fs_type</i> [-m...]]]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>lucreate</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature and its associated terminology.</p> <p>The <code>lucreate</code> command offers a set of command line options that enable you to perform the following functions:</p> <ul style="list-style-type: none"> <li>■ Create a new boot environment (BE), based on the current BE.</li> <li>■ Create a new BE, based on a BE other than the current BE.</li> <li>■ Join or separate the file systems of a BE onto a new BE. For example, join <code>/var</code> and <code>/opt</code> under <code>/</code>, or separate these directories to be mounted under different disk slices.</li> <li>■ Create the file systems for a BE, but leave those file systems unpopulated.</li> </ul> <p>You can perform the preceding functions using only <code>lucreate</code> command-line options or you can enter a set of options that will automatically invoke an FMLI-based interface that provides curses-based screens for Live Upgrade administration.</p> <p>The creation of a BE includes selecting the disk or device slices for all the mount points of the BE. You can also change the mount points of the BE using the <code>SPLIT</code> and <code>MERGE</code> functions of the FMLI-based configuration screen.</p> <p>Upon successful creation of a BE, you can use <code>lustatus(1M)</code> to view the state of that BE and <code>lufslst(1M)</code> to view the BE's file systems. You use <code>luupgrade(1M)</code> to upgrade the OS on that BE and <code>luactivate(1M)</code> to make a BE active, that is, designate it as the BE to boot from at the next reboot of the system.</p> <p>The <code>lucreate</code> command makes a distinction between the file systems that contain the OS—<code>/</code>, <code>/usr</code>, <code>/var</code>, and <code>/opt</code>—and those that do not, such as <code>/export</code>, <code>/home</code>, and other, user-defined file systems. The file systems in the first category cannot be shared between the source BE and the BE being created; they are always copied from the source BE to the target BE. By contrast, the user-defined file systems are shared by default. For Live Upgrade purposes, the file systems that contain the OS are referred to as non-shareable file systems; other file systems are referred to as shareable. A non-shareable file system listed in the source BE's <code>vfstab</code> is always copied to a new BE. For a shareable file system, if you specify a destination slice, the file system is copied. If you do not, the file system is shared.</p> <p>Except for a special use of the <code>-s</code> option, described below, you must have a source BE for the creation of a new BE. By default, it is the current BE. You can use the <code>-s</code> option to specify a BE other than the current BE.</p> |

## lucreate(1M)

By default, all swap partitions on a source BE are shared between the source and target BE. You can use the `-m` option (see below) to specify a subset of swap partitions on a source BE for sharing with a target BE.

The `lucreate` command requires root privileges.

### OPTIONS

The `lucreate` command has the options listed below. Note that a BE name must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of `sh(1)`. The BE name can contain only single-byte, 8-bit characters.

Omission of `-m` or `-M` options (described below) in an `lucreate` command line invokes the FMLI-based interface, which allows you to select disk or device slices for a BE.

#### `-c BE_name`

Assigns the name `BE_name` to the current BE. This option is required only when the first BE is created. For the first time you run `lucreate`, if you omit `-c` you are prompted to name the current BE. If you use the `-c` option following the first BE creation, you receive an error message.

#### `-C (boot_device | -)`

Required when you have a mirrored root device on the source BE. Specifies the physical boot device the source BE is booted from. When you use `-` (hyphen) with the `-C` option, `lucreate` attempts to figure out the boot device. If you specify `boot_device`, you override this automatic lookup. When you specify `boot_device`, you are queried:

```
Is the physical device devname the boot device for
the logical device devname?
```

If you respond `y`, the command proceeds. With the `-C -`, the preceding query is suppressed. With either form of `-C`, if `lucreate` cannot find the boot device, you receive an error message. Use of the `-C -` form is a safe choice, because `lucreate` either finds the correct boot device or gives you the opportunity to specify that device in a subsequent command.

#### `-l error_log`

Error messages and other status messages are sent to `error_log`, in addition to where they are sent in your current environment.

#### `-m mountpoint:device:fs_type [-m mountpoint:device:fs_type] ...`

Specifies the `vfstab(4)` information for the new BE. The file systems specified as arguments to `-m` can be on the same disk or can be spread across multiple disks.

`mountpoint` can be any valid mount point or `-` (hyphen), indicating a swap partition. The `device` field can be one of the following:

- The name of a disk device, of the form `/dev/dsk/cnumtnumdnumsnm`.
- The keyword `merged`, indicating that the file system at the specified mount point is to be merged with its parent.

The *fs\_type* field can be *ufs*, indicating a UFS file system; *vxfs*, indicating a Veritas file system; or *swap*, indicating a swap file system.

At minimum, you must specify one disk or device slice, for root. You can do this with *-m*, *-M* (described below), or in the FMLI-based interface. You must specify an *-m* argument for each file system you want to create on a new BE. For example, if you have three file systems on a source BE (say, */*, */usr*, and */var*) and want these three entities as separate file systems on a new BE, you must specify three *-m* arguments. If you were to specify only one, in our example, */*, */usr*, and */var* would be merged on the new BE into a single file system, under */*.

When using the *-m* option to specify swap partition(s), you can designate only swap partitions (all or a subset) on the source BE. Any swap assignment made with *-m* replaces (that is, does not add to) existing swap assignments. See EXAMPLES, below.

**-M *slice\_list***

List of *-m* options, collected in the file *slice\_list*. Specify these arguments in the format specified for *-m*. Comment lines, beginning with a hash mark (#), are ignored. The *-M* option is useful where you have a long list of file systems for a BE. Note that you can combine *-m* and *-M* options. For example, you can store swap partitions in *slice\_list* and specify */* and */usr* slices with *-m*.

The *-m* and *-M* options support the listing of multiple slices for a given mount point. In processing these slices, *lucreate* skips any unavailable slices and selects the first available slice. See EXAMPLES.

**-n *BE\_name***

The name of the BE to be created. *BE\_name* must be unique on a given system.

**-o *outfile***

All command output is sent to *outfile*, in addition to where it is sent in your current environment.

**-s (*-* | *BE\_name*)**

Source for the creation of the new BE. This option enables you to use a BE other than the current BE as the source for creation of a new BE. If you specify a hyphen (-) as an argument to *-s*, *lucreate* creates the new BE, but does not populate it. You can then use *lumake(1M)* or *luupgrade(1M)* to populate the BE. This option is especially useful for installing a flash archive. See *flar(1M)*.

**EXAMPLES**

The *lucreate* command produces copious output. In the following examples, this output is not reproduced, except where it is needed for clarity.

**EXAMPLE 1** Creating a New Boot Environment for the First Time

The following command sequence creates a new boot environment on a machine on which a BE has never been created. Note that, in the first command, the *-c* option is omitted.

## lucreate(1M)

### EXAMPLE 1 Creating a New Boot Environment for the First Time (Continued)

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
lucreate: Please wait while your system configuration is determined.
lucreate: No name for Current BE.
lucreate: ERROR: The current BE is not named - please provide the name
to use for the current BE with the <-c> option.
```

The same command is entered, with the addition of `-c`:

```
lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following creation of a BE, you use `luupgrade(1M)` to upgrade the OS on the new BE and `luactivate(1M)` to make that BE the BE you will boot from upon the next reboot of your machine. Note that the swap partition and all shareable file systems for `first_disk` will be available to (shared with) `second_disk`.

```
luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
many lines of output
luupgrade: Upgrade of Boot Environment <second_disk> successful.

luactivate second_disk
```

See `luupgrade(1M)` and `luactivate(1M)` for descriptions of those commands.

### EXAMPLE 2 Creating a BE using a Source Other than the Current BE

The following command uses the `-s` option to specify a source BE other than the current BE.

```
lucreate -s third_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

### EXAMPLE 3 Creating a BE from a Flash Archive

Performing this task involves use of `lucreate` with the `-s -` option and `luupgrade`.

```
lucreate -s - -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
brief messages
lucreate: Creation of Boot Environment <second_disk> successful.
```

With the `-s` option, the `lucreate` command completes its work within seconds. At this point, you can use `luupgrade` to install the flash archive:

```
luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \

```

**EXAMPLE 3** Creating a BE from a Flash Archive (Continued)

```
-J "archive_location http://example.com/myflash.flar"
```

See `luupgrade(1M)` for a description of that command.

**EXAMPLE 4** Using Swap Partitions on Multiple Disks

The command below creates a BE on a second disk and specifies the sharing of swap partitions on both the first and second disks. Note that the current boot environment must already be using `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` (on the second disk) as its swap partitions before entering this command.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
-m -:/dev/dsk/c0t0d0s1:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following completion of the preceding command, the BE `second_disk` will use both `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` as swap partitions. These swap assignments take effect only after booting from `second_disk`. If you have a long list of swap partitions, it is useful to use the `-M` option, as shown below.

**EXAMPLE 5** Using a Combination of `-m` and `-M` Options

In this example, a list of swap partitions is collected in the file `/etc/lu/swapslices`. The location and name of this file is user-defined. The contents of `/etc/lu/swapslices`:

```
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t4d0s2:swap
-:/dev/dsk/c0t5d0s2:swap
-:/dev/dsk/c1t3d0s2:swap
-:/dev/dsk/c1t4d0s2:swap
-:/dev/dsk/c1t5d0s2:swap
```

This file is specified in the following command:

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-M /etc/lu/swapslices -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The BE `second_disk` will swap onto the partitions specified in `/etc/lu/swapslices`. As with the previous example, the current BE must already be using the swap partitions specified on the command line before you enter the `lucreate` command.

## lucreate(1M)

### EXAMPLE 6 Copying Versus Sharing

The following command copies the user file system `/home` (in addition to the non-shareable file systems `/` and `/usr`) from the current BE to the new BE:

```
lucreate /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /home:/dev/dsk/c0t4d0s4:ufs -n second_disk
```

The following command differs from the preceding in that the `-m` option specifying a destination for `/home` is omitted. The result of this is that `/home` will be shared between the current BE and the BE `second_disk`.

```
lucreate /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
```

### EXAMPLE 7 Invoking FMLI-based Interface

The command below, by omitting `-m` or `-M` options, invokes the FMLI-based interface for Live Upgrade operations. See `lu(1M)` for a description of this interface.

```
lucreate -n second_disk
```

The preceding command uses the current BE as the source for the target BE `second_disk`. In the FMLI interface, you can specify the target disk slices for `second_disk`. The following command is a variation on the preceding:

```
lucreate -n second_disk -s third_disk
```

In the preceding command, a source for the target BE is specified. As before, the FMLI interface comes up, enabling you to specify target disk slices for the new BE.

### EXAMPLE 8 Merging File Systems

The command below merges the `/usr/opt` file system into the `/usr` file system. First, here are the disk slices in the BE `first_disk`, expressed in the format used for arguments to the `-m` option:

```
:/dev/dsk/c0t4d0s0:ufs
/usr:/dev/dsk/c0t4d0s1:ufs
/usr/opt:/dev/dsk/c0t4d0s3:ufs
```

The following command creates a BE `second_disk` and performs the merge operation, merging `/usr/opt` with its parent, `/usr`.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /usr/opt:merged:ufs -n second_disk
```

### EXAMPLE 9 Splitting a File System

Assume a source BE with `/`, `/usr`, and `/var` all mounted on the same disk slice. The following command creates a BE `second_disk` that has `/`, `/usr`, and `/var` all mounted on different disk slices.

**EXAMPLE 9** Splitting a File System *(Continued)*

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
/var:/dev/dsk/c0t4d0s3:ufs -n second_disk
```

This separation of a file system's (such as root's) components onto different disk slices is referred to as splitting a file system.

**EXAMPLE 10** Specifying Alternative Slices

The following command uses multiple `-m` options as alternative disk slices for the new BE `second_disk`.

```
lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /:/dev/dsk/c0t4d0s1:ufs \
-m /:/dev/dsk/c0t4d0s5:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The preceding command specifies three possible disk slices, `s0`, `s1`, and `s5` for the `/` file system. `lucreate` selects the first one of these slices that is not being used by another BE. Note that the `-s` option is omitted, meaning that the current BE is the source BE for the creation of the new BE.

**EXIT STATUS** The following exit values are returned:

0           Successful completion.  
>0          An error occurred.

**FILES** `/etc/lutab` list of BEs on the system

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWluu         |

**SEE ALSO** `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslis(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

**NOTES** When splitting a directory into multiple mount points, hard links are not maintained across file systems. For example, if `/usr/test1/buglist` is hard linked to `/usr/test2/buglist`, and `/usr/test1` and `/usr/test2` are split into separate file systems, the link between the files will no longer exist. `lucreate` issues a warning message to that effect and a symbolic link is created to replace the lost hard link.

## lucreate(1M)

lucreate cannot prevent you from making invalid configurations with respect to non-shareable file systems. For example, you could enter an `lucreate` command that would create separate file systems for `/` and `/kernel`—an invalid division of `/`. When creating file systems for a boot environment, the rules are identical to the rules for creating file systems for the Solaris operating environment.

| <b>NAME</b>        | lucurr – display the name of the active boot environment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/lucurr [-l <i>error_log</i>] [-m <i>mount_point</i>] [-o <i>outfile</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>lucurr</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lucurr</code> command displays the name of the currently running boot environment (BE). If no BEs are configured on the system, <code>lucurr</code> displays the message "No Boot Environments are defined". Note that <code>lucurr</code> reports only the name of the current BE, not the BE that will be active upon the next reboot. Use <code>lustatus(1M)</code> for this information.</p> <p>The <code>lucurr</code> command requires root privileges.</p>                                            |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The <code>lucurr</code> command has the following options:</p> <p><code>-l <i>error_log</i></code>      Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p><code>-m <i>mount_point</i></code>      Returns the name of the BE that owns <i>mount_point</i>. This can be a mount point of the current BE or the mount point of a BE other than the current BE. If the latter, the file system of the BE must have been mounted with <code>lumount(1M)</code> or <code>mount(1M)</code> before entering this option.</p> <p><code>-o <i>outfile</i></code>      All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p> |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>&gt;0          An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/lutab</code> list of BEs on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
|                    | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWluu</td> </tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWluu |

| <b>SYNOPSIS</b>    | <b>ludelete</b> [-l <i>error_log</i> ] [-o <i>outfile</i> ] <i>BE_name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>ludelete</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>ludelete</code> command deletes all records associated with a boot environment (BE) from <code>/etc/lutab</code> (see <code>lutab(4)</code>) on all defined complete BEs. A complete BE is one that is not participating in an <code>lucreate(1M)</code>, <code>luupgrade(1M)</code>, or <code>lucompare(1M)</code> operation. Use <code>lustatus(1M)</code> to determine a BE's status. You can delete neither the active BE, nor the BE that is activated upon the next reboot. Also, you cannot upgrade a BE that has file systems mounted with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The <code>ludelete</code> command has the following options:</p> <p>-l <i>error_log</i>      Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p>-o <i>outfile</i>        All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>OPERANDS</b>    | <i>BE_name</i> Name of the BE to be deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                  Successful completion.</p> <p>&gt;0                An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/lutab</code> list of BEs on the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |

- NAME** lufslis – list configuration of a boot environment
- SYNOPSIS** **lufslis** [-l *error\_log*] [-o *outfile*] *BE\_name*
- DESCRIPTION** The **lufslis** command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See **live\_upgrade(5)** for a description of the Live Upgrade feature.
- The **lufslis** command lists the configuration of a boot environment (BE). The output contains the disk slice (file system), file system type, and file system size for each BE mount point.
- The following is an example of **lufslis** output.
- ```
# lufslis BE_name
Filesystem                fstype          size(Mb) Mounted on
-----
/dev/dsk/c0t0d0s1         swap            512.11 -
/dev/dsk/c0t4d0s3         ufs             3738.29 /
/dev/dsk/c0t4d0s4         ufs             510.24 /opt
```
- File system type can be **ufs**, **swap**, or **vxfs**, for a Veritas file system. Under the **Filesystem** heading can be a disk slice or a logical device, such as a disk metadvice used by volume management software.
- The **lufslis** command requires root privileges.
- OPTIONS** The **lufslis** command has the following options:
- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
 - o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- OPERANDS** *BE_name* Name of the BE for which file systems are to be reported. You cannot specify a BE that is involved in another Live Upgrade operation.
- EXIT STATUS** The following exit values are returned:
- 0 Successful completion.
 - >0 An error occurred.
- FILES** /etc/lutab list of BEs on the system
- ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

NAME	lumake – populate a boot environment												
SYNOPSIS	<p>lumake [-l <i>error_log</i>] -t <i>time</i> [-o <i>outfile</i>] [-s <i>source_BE</i>] -n <i>BE_name</i> [-m <i>email_address</i>]</p> <p>lumake [-l <i>error_log</i>] [-o <i>outfile</i>] [-s <i>source_BE</i>] -n <i>BE_name</i></p>												
DESCRIPTION	<p>The lumake command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The lumake command populates (that is, copies files to) the file systems of a specified boot environment (BE) by copying files from the corresponding file systems of the active or a source (-s) BE. Any existing data on the target BE are destroyed. All file systems on the target BE are re-created.</p> <p>The target BE must already exist. Use <code>lucreate(1M)</code> to create a new BE.</p> <p>The lumake command requires root privileges.</p>												
OPTIONS	<p>The lucompare command has the following options:</p> <table border="0"> <tr> <td style="vertical-align: top;">-t <i>time</i></td> <td>Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation.</td> </tr> <tr> <td style="vertical-align: top;">-l <i>error_log</i></td> <td>Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</td> </tr> <tr> <td style="vertical-align: top;">-o <i>outfile</i></td> <td>All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</td> </tr> <tr> <td style="vertical-align: top;">-m <i>email_address</i></td> <td>Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i>. You can use this option only in conjunction with -t.</td> </tr> <tr> <td style="vertical-align: top;">-n <i>BE_name</i></td> <td>Name of the BE to be populated.</td> </tr> <tr> <td style="vertical-align: top;">-s <i>source_BE</i></td> <td>The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status.</td> </tr> </table>	-t <i>time</i>	Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation.	-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.	-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.	-m <i>email_address</i>	Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i> . You can use this option only in conjunction with -t.	-n <i>BE_name</i>	Name of the BE to be populated.	-s <i>source_BE</i>	The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status.
-t <i>time</i>	Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the <code>at(1)</code> man page. At any time, you can have only one Live Upgrade operation scheduled. You can use <code>lucancel(1M)</code> to cancel a scheduled lumake operation.												
-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.												
-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.												
-m <i>email_address</i>	Allows you to email lumake output to a specified address upon command completion. There is no checking of <i>email_address</i> . You can use this option only in conjunction with -t.												
-n <i>BE_name</i>	Name of the BE to be populated.												
-s <i>source_BE</i>	The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use <code>lustatus(1M)</code> to determine a BE's status.												
EXIT STATUS	<p>The following exit values are returned:</p> <table border="0"> <tr> <td style="vertical-align: top;">0</td> <td>Successful completion.</td> </tr> <tr> <td style="vertical-align: top;">>0</td> <td>An error occurred.</td> </tr> </table>	0	Successful completion.	>0	An error occurred.								
0	Successful completion.												
>0	An error occurred.												

lumake(1M)

FILES /etc/lutab list of BEs on the system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

SEE ALSO `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslist(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

NAME	lumount, luumount – mount or unmount all file systems in a boot environment				
SYNOPSIS	<pre>lumount [-l <i>error_log</i>] [-o <i>outfile</i>] <i>BE_name</i> [<i>mount_point</i>]</pre> <pre>luumount [-l <i>error_log</i>] [-o <i>outfile</i>] <i>BE_name</i></pre>				
DESCRIPTION	<p>The lumount and luumount commands are part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The lumount and luumount commands enable you to mount or unmount all of the filesystems in a boot environment (BE). This allows you to inspect or modify the files in a BE while that BE is not active. By default, lumount mounts the file systems on a mount point of the form <code>/.alt.<num></code>, where <code><num></code> is a random number.</p> <p>The lumount and luumount commands require root privileges.</p>				
OPTIONS	<p>The lumount and luumount commands have the following options:</p> <p><code>-l <i>error_log</i></code> Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</p> <p><code>-o <i>outfile</i></code> All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</p>				
OPERANDS	<table border="0"> <tr> <td style="vertical-align: top;"><i>BE_name</i></td> <td>Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code>. Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>).</td> </tr> <tr> <td style="vertical-align: top;"><i>mount_point</i></td> <td>For lumount only, a mount point to use instead of the default <code>/.alt.<num></code>. If <i>mount_point</i> does not exist, lumount creates it.</td> </tr> </table>	<i>BE_name</i>	Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code> . Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>).	<i>mount_point</i>	For lumount only, a mount point to use instead of the default <code>/.alt.<num></code> . If <i>mount_point</i> does not exist, lumount creates it.
<i>BE_name</i>	Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code> . Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>).				
<i>mount_point</i>	For lumount only, a mount point to use instead of the default <code>/.alt.<num></code> . If <i>mount_point</i> does not exist, lumount creates it.				
EXAMPLES	<p>EXAMPLE 1 Specifying a Mount Point</p> <p>The following command creates the mount point <code>/test</code> and mounts the file systems of the BE <code>second_disk</code> on <code>/test</code>.</p> <pre># lumount second_disk /test /test</pre> <p>You can then <code>cd</code> to <code>/test</code> to view the file systems of <code>second_disk</code>.</p>				

lumount(1M)

EXAMPLE 2 Unmounting File Systems

The following command unmounts the file systems of the BE `second_disk`. In this example, we `cd` to `/` to ensure we are not in any of the file systems in `second_disk`.

```
# cd /
# luumount second_disk
#
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

NAME	lurename – change the name of a boot environment								
SYNOPSIS	lurename -e <i>BE_name</i> -n <i>new_name</i> [-l <i>error_log</i>] [-o <i>outfile</i>]								
DESCRIPTION	<p>The lurename command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The lurename command renames the boot environment (BE) <i>BE_name</i> to <i>new_name</i>.</p> <p>The string <i>new_name</i> must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of <code>sh(1)</code>. The BE name can contain only single-byte, 8-bit characters. Also, <i>new_name</i> must be unique on the system.</p> <p>A BE must have the status “complete” before you rename it. Use <code>lustatus(1M)</code> to determine a BE’s status. Also, you cannot rename a BE that has file systems mounted with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> <p>Renaming a BE is often useful when you upgrade the BE from one Solaris release to another. For example, following an operating system upgrade, you might rename the BE <code>solaris7</code> to <code>solaris8</code>.</p> <p>The lurename command requires root privileges.</p>								
OPTIONS	<p>The lurename command has the options listed below.</p> <table> <tr> <td>-e <i>BE_name</i></td> <td>Name of the BE whose name you want to change.</td> </tr> <tr> <td>-l <i>error_log</i></td> <td>Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</td> </tr> <tr> <td>-n <i>new_name</i></td> <td>New name of the BE. <i>new_name</i> must be unique on a given system.</td> </tr> <tr> <td>-o <i>outfile</i></td> <td>All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</td> </tr> </table>	-e <i>BE_name</i>	Name of the BE whose name you want to change.	-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.	-n <i>new_name</i>	New name of the BE. <i>new_name</i> must be unique on a given system.	-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.
-e <i>BE_name</i>	Name of the BE whose name you want to change.								
-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.								
-n <i>new_name</i>	New name of the BE. <i>new_name</i> must be unique on a given system.								
-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.								
EXIT STATUS	<p>The following exit values are returned:</p> <table> <tr> <td>0</td> <td>Successful completion.</td> </tr> <tr> <td>>0</td> <td>An error occurred.</td> </tr> </table>	0	Successful completion.	>0	An error occurred.				
0	Successful completion.								
>0	An error occurred.

NAME	lustatus – display status of boot environments																														
SYNOPSIS	lustatus [-l <i>error_log</i>] [-o <i>outfile</i>] [<i>BE_name</i>]																														
DESCRIPTION	<p>The <code>lustatus</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>lustatus</code> command displays the status information of the boot environment (BE) <i>BE_name</i>. If no BE is specified, the status information for all BEs on the system is displayed.</p> <p>The headings in the <code>lustatus</code> information display are described as follows:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>BE_name</i></td> <td>Name of the BE.</td> </tr> <tr> <td>Complete</td> <td>Indicates whether a BE is able to be booted. Any current activity or failure in an <code>lucreate()</code> or <code>luupgrade(1M)</code> operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete.</td> </tr> <tr> <td>Active</td> <td>Indicates whether the BE is currently active. The “active” BE is the one currently booted.</td> </tr> <tr> <td>ActiveOnReboot</td> <td>Indicates whether the BE becomes active upon next reboot of the system.</td> </tr> <tr> <td>CopyStatus</td> <td>Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of SCHEDULED or COMPARING (from <code>lucompare(1M)</code>) prevents you performing Live Upgrade copy, rename, or upgrade operations.</td> </tr> </table> <p>The following is an example <code>lustatus</code> display:</p> <table border="0"> <thead> <tr> <th style="text-align: left;"><i>BE_name</i></th> <th style="text-align: left;">Complete</th> <th style="text-align: left;">Active</th> <th style="text-align: left;">ActiveOnReboot</th> <th style="text-align: left;">CopyStatus</th> </tr> </thead> <tbody> <tr> <td>disk_a_S7</td> <td>yes</td> <td>yes</td> <td>yes</td> <td>-</td> </tr> <tr> <td>disk_b_S7database</td> <td>yes</td> <td>no</td> <td>no</td> <td>SCHEDULED</td> </tr> <tr> <td>disk_b_S8</td> <td>no</td> <td>no</td> <td>no</td> <td>-</td> </tr> </tbody> </table> <p>Note that you could not perform copy, rename, or upgrade operations on <code>disk_b_S8</code>, because it is not complete, nor on <code>disk_b_S7database</code>, because a Live Upgrade operation is pending.</p> <p>The <code>lustatus</code> command requires root privileges.</p>	<i>BE_name</i>	Name of the BE.	Complete	Indicates whether a BE is able to be booted. Any current activity or failure in an <code>lucreate()</code> or <code>luupgrade(1M)</code> operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete.	Active	Indicates whether the BE is currently active. The “active” BE is the one currently booted.	ActiveOnReboot	Indicates whether the BE becomes active upon next reboot of the system.	CopyStatus	Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of SCHEDULED or COMPARING (from <code>lucompare(1M)</code>) prevents you performing Live Upgrade copy, rename, or upgrade operations.	<i>BE_name</i>	Complete	Active	ActiveOnReboot	CopyStatus	disk_a_S7	yes	yes	yes	-	disk_b_S7database	yes	no	no	SCHEDULED	disk_b_S8	no	no	no	-
<i>BE_name</i>	Name of the BE.																														
Complete	Indicates whether a BE is able to be booted. Any current activity or failure in an <code>lucreate()</code> or <code>luupgrade(1M)</code> operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete.																														
Active	Indicates whether the BE is currently active. The “active” BE is the one currently booted.																														
ActiveOnReboot	Indicates whether the BE becomes active upon next reboot of the system.																														
CopyStatus	Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of SCHEDULED or COMPARING (from <code>lucompare(1M)</code>) prevents you performing Live Upgrade copy, rename, or upgrade operations.																														
<i>BE_name</i>	Complete	Active	ActiveOnReboot	CopyStatus																											
disk_a_S7	yes	yes	yes	-																											
disk_b_S7database	yes	no	no	SCHEDULED																											
disk_b_S8	no	no	no	-																											
OPTIONS	<p>The <code>lustatus</code> command has the following options:</p> <table border="0"> <tr> <td style="padding-right: 20px;">-l <i>error_log</i></td> <td>Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment.</td> </tr> <tr> <td>-o <i>outfile</i></td> <td>All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment.</td> </tr> </table>	-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.	-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.																										
-l <i>error_log</i>	Error and status messages are sent to <i>error_log</i> , in addition to where they are sent in your current environment.																														
-o <i>outfile</i>	All command output is sent to <i>outfile</i> , in addition to where it is sent in your current environment.																														

lustatus(1M)

OPERANDS *BE_name* Name of the BE for which to obtain status. If *BE_name* is omitted, lustatus displays status for all BEs in the system.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES /etc/lutab list of BEs on the system

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

SEE ALSO lu(1M), luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), lucurr(1M), ludelete(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)

NAME	luupgrade – installs, upgrades, and performs other functions on software on a boot environment
SYNOPSIS	luupgrade [-iIufpPtTcC] [<i>options</i>]
DESCRIPTION	<p>The <code>luupgrade</code> command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See <code>live_upgrade(5)</code> for a description of the Live Upgrade feature.</p> <p>The <code>luupgrade</code> command enables you to install software on a specified boot environment (BE). Specifically, <code>luupgrade</code> performs the following functions:</p> <ul style="list-style-type: none"> ■ Upgrades an operating system image on a BE (-u option). The source for the image can be any valid Solaris installation medium. ■ Run an installer program to install software from an installation medium (-i option). ■ Extract a flash archive onto a BE (-f option). (See <code>flar(1M)</code>.) ■ Add a package to (-p) or remove a package from (-P) a BE. ■ Add a patch to (-t) or remove a patch from (-T) a BE. ■ Check (-c) or obtain information about (-I) packages. ■ Check an operating system installation medium (-c). <p>Before using <code>luupgrade</code>, you must have created a BE, using either the <code>lucreate(1M)</code> command or <code>lu(1M)</code>, the FMLI-based user interface. You can upgrade only BEs other than the current BE.</p> <p>The functions described in the preceding list each has its own set of options, which are described separately for each function.</p> <p>Note that, for successful completion of an <code>luupgrade</code> operation, the status of a BE must be complete, as reported by <code>lustatus(1M)</code>. Also, the BE must not have any mounted disk slices, mounted either with <code>lumount(1M)</code> or <code>mount(1M)</code>.</p> <p>The <code>luupgrade</code> command requires root privileges.</p> <p>Options that Apply to All Uses</p> <p>The following options are available for all uses of <code>luupgrade</code>:</p> <ul style="list-style-type: none"> -l <i>error_log</i> Error and status messages are sent to <i>error_log</i>, in addition to where they are sent in your current environment. -o <i>outfile</i> All command output is sent to <i>outfile</i>, in addition to where it is sent in your current environment. -N Dry-run mode. Enables you to determine whether your command arguments are correctly formed. Does not apply to the -c (check medium) function. <p>Upgrading an Operating System Image</p> <p>The syntax for this use of <code>luupgrade</code> is as follows:</p>

luupgrade(1M)

```
luupgrade -u -n BE_name -s os_image_path [ -j profile_path ]  
[ -l error_log ] [ -o outfile ] [-N]
```

The first option, `-u`, indicates the function to perform—to install an OS image. The remaining options, shown above, are described as follows:

`-n BE_name` Name of the BE to receive an OS upgrade.

`-s os_image_path` Path name of a directory containing an OS image. This can be a directory on an installation medium such as a CD-ROM or can be an NFS or UFS directory.

`-j profile_path` Path to a JumpStart profile. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software.

Note that if you are upgrading from a medium with multiple components, such as from multiple CDs, use `luupgrade` with the `-i` option, as described in the section below, to install software from the second and any following media.

Running an Installer Program

The syntax for this use of `luupgrade` is as follows:

```
luupgrade -i -n BE_name -s installation_medium [ -N ]  
[ -O "installer_options" ] [ -l error_log ] [ -o outfile ]
```

The first option, `-i`, indicates the function to perform—to run an installer program on the installation specified with `-s`. The remaining options, shown above, are described as follows:

`-n BE_name` Name of the BE on which software is to be installed.

`-O "installer_options"` Options passed directly to the Solaris installer program. See `installer(1M)` for descriptions of the installer options.

`-s installation_medium` Path name of an installation medium. This can be a CD, or an NFS or UFS directory.

With the `-i` option, `luupgrade` looks for an installation program on the specified medium and runs that program.

The `-i` option has a special use when you use the `-u` option, described above, to install software from a multiple-component medium, such as multiple CDs. See **EXAMPLES**.

Upgrading from a Flash Archive

The syntax for this use of `luupgrade` is as follows:

```
luupgrade -f -n BE_name -s os_image_path ( -a archive | -j profile_path  
| -J "profile" ) [ -l error_log ] [ -o outfile ] [ -N ]
```

The first option, `-f`, indicates the function to perform—to upgrade an OS from a flash archive. The remaining options, shown above, are described as follows:

`-n BE_name`
Name of the BE to receive an OS installation.

- s *os_image_path*
Path name of a directory containing an OS image. This can be a directory on an installation medium, such as a CD-ROM, or can be an NFS or UFS directory.
- a *archive*
Path to the flash archive when the archive is available on the local file system. You must specify one of -a, -j, or -J.
- j *profile_path*
Path to a JumpStart profile that is configured for a flash installation. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j, or -J.
- J "*profile*"
Entry from a JumpStart profile that is configured for a flash installation. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j, or -J.

Add or Remove Packages

The `luupgrade` command uses `-p` to add a package and `-P` to remove a package. The syntax is as follows:

For adding packages:

```
luupgrade -p -n BE_name -s packages_path [ -l error_log ] [ -o outfile ]
[ -O "pkgadd_options" ] [ -a admin ] [ pkginst [ pkginst... ] ] [ -N ]
```

For removing packages:

```
luupgrade -P -n BE_name [ -l error_log ] [ -o outfile ]
[ -O "pkgrm_options" ] [ pkginst [ pkginst... ] ] [ -N ]
```

The first option, `-p`, to add packages, or `-P` to remove packages, indicates the function to perform. The remaining options, shown above, are described as follows:

- n *BE_name*
Name of the BE to which packages will be added or from which packages will be removed.
- s *packages_path*
(For adding packages only.) Path name of a directory containing packages to add. You can substitute `-d` for `-s`. The `-d` support is for `pkgadd(1M)` compatibility.
- d *packages_path*
Identical to `-s`. Use of `-s` is recommended.
- O "*pkgadd_options*" or "*pkgrm_options*"
Options passed directly to `pkgadd` (for `-p`) or `pkgrm` (for `-P`). See `pkgadd(1M)` and `pkgrm(1M)` for descriptions of the options for those commands.
- a *admin*
(For adding packages only.) Path to an admin file. Identical to the `pkgadd -a` option. Use of the `-a` option here is identical to `-O "-a admin"`

luupgrade(1M)

Add or Remove Patches

pkginst [*pkginst...*]

Zero or more packages to add or remove. For adding packages, the default is to add all of the packages specified with the `-s` option, above. Separate multiple package names with spaces.

The `luupgrade` command uses `-t` to add a patch and `-T` to remove a patch. The syntax is as follows:

For adding patches:

```
luupgrade -t -n BE_name -s patch_path [ -l error_log ][ -o outfile ]  
[ -O "patchadd_options" ] [ patch_name [ patch_name... ] ] [ -N ]
```

For removing patches:

```
luupgrade -T -n BE_name [ -l error_log ][ -o outfile ]  
[ -O "patchrm_options" ] [ patch_name [ patch_name... ] ] [ -N ]
```

The first option, `-t`, to add patches, or `-T` to remove patches, indicates the function to perform. The remaining options, shown above, are described as follows:

`-n BE_name`

Name of the BE to which patches will be added or from which patches will be removed.

`-s patch_path`

(For adding patches only.) Path name of a directory containing patches to add.

`-O "patchadd_options" or "patchrm_options"`

Options passed directly to `patchadd` (for `-p`) or `patchrm` (for `-P`). See `patchadd(1M)` or `patchrm(1M)` for a description of these options.

patch_name [*patch_name...*]

Zero or more patches to add or remove. For adding patches, the default is to add all of the patches specified with the `-s` option, above. Separate multiple patch names with spaces.

Check or Return Information on Packages

Use the `-C` to perform a `pkgchk(1M)` on all or the specified packages on a BE. Use the `-I` option to perform a `pkginfo(1)`.

For performing a `pkgchk`:

```
luupgrade -C -n BE_name [ -l error_log ][ -o outfile ]  
[ -O "pkgchk_options" ][ pkginst [ pkginst... ] ] [ -N ]
```

For performing a `pkginfo`:

```
luupgrade -I -n BE_name [ -l error_log ][ -o outfile ]  
[ -O "pkginfo_options" ][ pkginst [ pkginst... ] ] [ -N ]
```

The first option, `-C`, for `pkgchk`, or `-I`, for `pkginfo`, indicates the function to perform. The remaining options, shown above, are described as follows:

`-n BE_name`
 Name of the BE on which packages will be checked or on whose packages information will be returned.

`-O "pkgchk_options" or "pkginfo_options"`
 Options passed directly to `pkgchk` (for `-C`) or `pkginfo` (for `-I`). See `pkgchk(1M)` or `pkginfo(1)` for a description of these options.

`pkginst [pkginst...]`
 Zero or more packages to check or for which to have information returned. If you omit package names, `luupgrade` returns information on all of the packages on the BE. Separate multiple package names with spaces.

Check an OS Installation Medium

With the `-c` option, `luupgrade` allows you to check that a local or remote medium, such as a CD, is a valid installation medium. The `-c` option returns useful information about the specified medium. The syntax for this use of `luupgrade` is as follows:

```
luupgrade -c -s path_to_medium [ -l error_log ] [ -o outfile ]
```

The first option, `-c`, indicates the function to perform—to check on an installation medium. The `-s` option, shown above, is described as follows:

`-s path_to_medium` Path name to an installation medium such as a CD-ROM.

EXAMPLES

EXAMPLE 1 Removing, then Adding Packages

The following example removes then adds a set of packages to a boot environment.

```
# luupgrade -P -n second_disk SUNWabc SUNWdef SUNWghi
```

Now, to add the same packages:

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
SUNWabc SUNWdef SUNWghi
```

The following command adds the `-O` option to the preceding command. This option passes arguments directly to `pkgadd`.

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
-O "-r /net/testmachine/export/responses" SUNWabc SUNWdef SUNWghi
```

See `pkgadd(1M)` for a description of the options for that command.

EXAMPLE 2 Upgrading to a New OS

The following example upgrades the operating environment on a boot environment.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
```

Following the command above you could enter the command below to activate the upgraded BE.

```
# luactivate second_disk
```

luupgrade(1M)

EXAMPLE 2 Upgrading to a New OS *(Continued)*

Then, upon the next reboot, `second_disk` would become the current boot environment. See `luactivate(1M)`.

EXAMPLE 3 Upgrading to a New OS from Multiple CDs

The following example is a variation on the preceding. The OS upgrade resides on two CDs. To begin the upgrade, you enter:

For SPARC machines:

```
# luupgrade -u -n second_disk -s /dev/cdrom/cdrom0/s0
```

For Intel Architecture (IA) machines, replace the `s0` in the argument to `-s` with `s2`.

When the installer is finished with the contents of the first CD, insert the next CD in the drive and enter the following:

```
# luupgrade -i -n second_disk -s /dev/cdrom/cdrom0
```

Note the use of `-i` rather than `-u` in the preceding. Were there additional CDs, you would enter the same command as the one immediately above.

If you are connected to the machine you are upgrading by a `tip(1)` line, you must use the `-O "-nodisplay"` option, as shown below:

```
# luupgrade -u -n second_disk -O "-nodisplay" -s /dev/cdrom/cdrom0/s0  
or s2 for IA machines
```

Insert next CD, then...

```
# luupgrade -i -n second_disk -O "-nodisplay" -s /dev/cdrom/cdrom0
```

EXAMPLE 4 Installing a New OS from a Flash Archive

The following example upgrades the operating environment on a boot environment, using a flash archive.

```
# luupgrade -f -n second_disk \  
-s /net/installmachine/export/solarisX/OS_image \  
-J "archive_location http://example.com/myflash.flar"
```

EXAMPLE 5 Obtaining Information on Packages

The following example runs a `pkgchk` on the packages `SUNWluu` and `SUNWlur`, passing to `pkgchk` the `-v` option.

```
# luupgrade -C -n second_disk -O "-v" SUNWluu SUNWlur
```

The following command runs `pkginfo` on the same set of packages:

```
# luupgrade -I -n second_disk -O "-v" SUNWluu SUNWlur
```

EXAMPLE 5 Obtaining Information on Packages (Continued)

For both commands, if the package names were omitted, `luupgrade` returns package information on all of the packages in the specified BE. See `pkgchk(1M)` and `pkginfo(1)` for a description of the options for those commands.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES `/etc/lutab` list of BEs on the system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

SEE ALSO `lu(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

WARNINGS For adding packages (`-p`), `luupgrade` requires packages that comply with the SVR4 Advanced Packaging Guidelines. While Sun packages conform to these guidelines, Sun cannot guarantee the conformance of packages from third-party vendors. A non-conformant package can cause the package-addition software in `luupgrade` to fail or, worse, alter the current BE.

luxadm(1M)

NAME	luxadm – administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices
SYNOPSIS	luxadm [<i>options...</i>] <i>subcommand</i> [<i>options...</i>] <i>enclosure</i> [, <i>dev</i>] <i>pathname...</i>
DESCRIPTION	<p>The luxadm program is an administrative command that manages the SENA, RSM, SPARCstorage Array subsystems, Sun Fire 880 internal storage subsystem, and individual FC_AL devices. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.</p> <p>The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.</p> <p>Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.</p>
Pathname	<p>Specify the device or controller by either a complete physical pathname or a complete logical pathname.</p> <p>For SENA, a typical physical pathname for a device is:</p> <pre>/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96, 0:a,raw</pre> <p>or</p> <pre>/devices/io-unit@f,e0200000/sbi@0,0/SUNW,socal@2,0/sf@0,0/ssd@34, 0:a,raw</pre> <p>For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es.</p> <p>The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:</p> <pre>2200002037000f96</pre> <p>See NOTES for more information on the WWN formats.</p>

For the SPARCstorage Array controller, a typical physical pathname is:

```
/devices/. . . /. . . /SUNW,soc@3,0/SUNW,pln@
    axxxxxx,xxxxxxx:ctlr
```

whereas, a typical physical pathname for an RSM controller is:

```
/devices/sbus@1f,0/QLGC,isp@1,10000:devctl
```

In order to make it easier to address the SPARCstorage Array or RSM controller, a logical pathname of the form *cN* is supported, where *N* is the logical controller number. luxadm uses the *cN* name to find an entry in the `/dev/rdisk` directory of a disk that is attached to the SPARCstorage Array or RSM controller. The `/dev/rdisk` entry is then used to determine the physical name of the SPARCstorage Array or RSM controller.

For a SPARCstorage Array disk, a typical physical pathname is:

```
/devices/. . . /. . . /SUNW,soc@3,0/SUNW,
    pln@xxxxxxx,xxxxxxx/ssd@0,0:c,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

For an RSM a typical physical pathname is:

```
/devices/sbus@1f,0/QLGC,isp@1,10000/sd@8,0:c,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c2t8d0s2
```

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@8,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdisk/c2t8d0s2
```

For individual FC_AL devices, a typical physical pathname is:

```
/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w2200002037049fc3,0:a,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

luxadm(1M)

Enclosure	<p>For SENA, a device may be identified by its enclosure name and slotname:</p> <p><i>box_name</i>[, <i>fslot_number</i>] <i>box_name</i>[, <i>rslot_number</i>]</p> <p><i>box_name</i> is the name of the SENA enclosure, as specified by the <i>enclosure_name</i> subcommand. When used without the optional <i>slot_number</i> parameter, the <i>box_name</i> identifies the SENA subsystem IB.</p> <p><i>f</i> or <i>r</i> specifies the front or rear slots in the SENA enclosure.</p> <p><i>slot_number</i> specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.</p> <p>For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:</p> <p><i>box_name</i> [, <i>sslot_number</i>] <i>box_name</i> is the name of the Sun Fire 880 enclosure, as specified by the <i>enclosure_name</i> subcommand. When used without the optional <i>slot_number</i> parameter, <i>box_name</i> identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use <i>s</i> to specify the disk slot number in the Sun Fire 880 internal storage subsystem, 0 - 11.</p> <p>See <code>disks(1M)</code> and <code>devlinks(1M)</code> for additional information on logical names for disks and subsystems.</p>
OPTIONS	<p>The following options are supported by all subcommands:</p> <p>-e Expert mode. This option is not recommended for the novice user.</p> <p>-v Verbose mode.</p> <p>Options that are specific to particular subcommands are described with the subcommand in the <code>USAGE</code> section.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>enclosure</i> The <i>box_name</i> of the SENA. or Sun Fire 880 internal storage subsystem.</p> <p><i>pathname</i> The logical or physical path of a SENA IB,, Sun Fire 880 internal storage subsystem, SPARCstorage Array or RSM controller (<i>cN</i> name) or disk device. <i>pathname</i> can also be the WWN of a SENA IB, SENA disk, or individual FC_AL device.</p>
Subcommands	<p><code>display enclosure[<i>dev</i>]... <i>pathname</i>...</code> <code>display -p <i>pathname</i>...</code> <code>display -r enclosure[<i>dev</i>]... <i>pathname</i>...</code> <code>display -v enclosure[<i>dev</i>]... <i>pathname</i>...</code> Displays enclosure or device specific data.</p>

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

-p

Displays performance information for the device or subsystem specified by *pathname*. This option only applies to subsystems that accumulate performance information.

-r

Displays error information for the FC_AL device specified by the *pathname*, or, if the path is a SENA, for all devices on the loop. The -r option only applies to SENA subsystems and individual FC_AL devices.

-v

Displays in verbose mode, including mode sense data.

`download [-s] [-w WWN] [-f filename_path] enclosure . .`

Download the prom image pointed to by *filename_path* to the SENA subsystem Interface Board unit, the Sun Fire 880 internal storage subsystem, or the SPARCstorage Array controllers specified by the enclosure or *pathname*. The SPARCstorage Array must be reset in order to use the downloaded code.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no filename is specified, the default prom image will be used. The default prom image for the SPARCstorage Array controller is in `usr/lib/firmware/ssa/ssafirmware`. The default prom image for the SENA is in the directory `usr/lib/locale/C/LC_MESSAGES` and is named `ibfirmware`

When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem resets and the downloaded code begins execution. The default firmware image for the Sun Fire 880 internal storage subsystem is in:

`/usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw`.

-s

Save. The -s option is used to save the downloaded firmware in the FEPRM. If -s is not specified, the downloaded firmware will not be saved across power cycles.

The -s option does not apply to the SPARCstorage Array controller as it *always* writes the downloaded firmware into the FEPRM.

The -s option does not apply to the Sun Fire 880 internal storage subsystem as it always stores downloaded firmware in the flash memory.

When using the -s option, the `download` subcommand modifies the FEPRM on the subsystem and should be used with *caution*.

`-w WWN`

Change the SPARCstorage Array controller's World Wide Name. *WWN* is a 12-digit hex number; leading zeros are required. The `-w` option applies only to the SPARCstorage Array. The new SPARCstorage Array controller's image will have the least significant 6 bytes of the 8-byte World Wide Name modified to *WWN*.

`enclosure_name new_name enclosure | pathname`

Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

`fc_s_download [-F] [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fc_s_download` *only* in single-user mode. Using `fc_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file`

When invoked without the `-f fcode-file` option, the current version of the fcode in each FC/S Sbus card is printed.

`-F`

Forcibly downloads the fcode, but the command still expects user confirmation before the download. The version of the FC/S Sbus Cards fcode that was released with this version of the Operating System is kept in the directory `usr/lib/firmware/fc_s` and is named `fc_s_fcode`.

`fc100_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fc100_s_download` *only* in single-user mode. Using `fc100_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file`

When invoked without the `-f` option, the current version of the fcode in each FC100/S Sbus card is printed.

`fcode_download -p`

`fcode_download -d dir-name`

Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command

determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use `fcode_download` to load FCode only in single-user mode. Using `fcode_download` to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-d dir-name`

Download the FCode files contained in the directory *dir-name* to the appropriate adapter cards.

`-p`

Prints the current version of FCode loaded on each card. No download is performed.

`inquiry enclosure[,dev] ... | pathname ...`

Display the inquiry information for the selected device specified by the enclosure or *pathname*.

`insert_device [enclosure,dev ...]`

Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, RSM, and individual FC_AL drives. RSM, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the RSM, only one controller can be specified. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

For the RSM, the following steps are taken:

- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform the user that the device can be safely inserted .
- Request confirmation from the user that the device has been inserted.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Create the logical device name for the new device.

`led enclosure,dev ... | pathname ...`

Display the current state of the LED associated with the disk specified by the enclosure or *pathname*. This subcommand only applies to subsystems that support this functionality.

luxadm(1M)

`led_blink enclosure,dev ... | pathname ...`

Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_off enclosure,dev ... | pathname ...`

Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

`led_on pathname ...`

Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

`power_off [-F] enclosure[,dev] ... | pathname ...`

`power_off pathname [enclosure-port] ... | controller tray-number`

When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When an Enclosure Services card within the SPARCstorage Array is addressed, the RSM tray is powered down. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

-F

The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

Warning: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal checks.

`power_on enclosure[,dev] ..`

Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA. There is no programmatic way to power on the SPARCstorage Array RSM tray. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

`probe [-p]`

Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

-p

Includes the physical pathname in the display.

`qlgc_s_download [-f fcode-file]`

Download the FCode contained in the file *fcode-file* into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use `qlgc_s_download` in single-user mode. Using `qlgc_s_download` to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-f *fcode-file*

When invoked without the -f option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

`release pathname`

Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk. If the pathname is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be released.

This subcommand is included for historical and diagnostic purposes only.

`remove_device [-F] enclosure[,dev] . . . | pathname . . .`

Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, RSM, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely removed.
- Request confirmation from the user that the device has been removed.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the (now removed) device back online.
- Remove the logical device name for the removed device.

For Multi-Hosted disk, the steps taken are:

- Issue the `luxadm remove_device` command on the first host. When prompted to continue, wait.
- Issue the `luxadm remove_device` command on the secondary hosts. When prompted to continue, wait.

luxadm(1M)

- Continue with the `remove_device` command on the first host. Remove the device when prompted to do so.
- Complete the `luxadm remove_device` command on the additional hosts.

-F

Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy* or *reserved*), to *force* the hotplugging operation.

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`replace_device [-F] pathname`

This subcommand applies only to the RSM. Refer to NOTES for limitations on hotplug operations. This subcommand guides the user interactively through the hot replacement of a device.

For the RSM, the steps taken are:

- Take the device offline.
- Quiesce the bus or buses which support quiescing and unquiescing.
- Inform user that the device can be safely replaced.
- Request confirmation from the user that the device has been replaced.
- Unquiesce the bus or buses which support quiescing and unquiescing.
- Bring the device back online.

-F

Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are *busy* or *reserved*, (that is, to *force* the hotplugging operation).

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`reserve pathname`

Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk. If the pathname is of the SPARCstorage Array controller, then all of the disks in the SPARCstorage Array will be reserved.

This subcommand is included for historical and diagnostic purposes only.

`set_boot_dev [-y] pathname`

Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the

PROM. The `-y` option can be used to run it non-interactively, in which case no confirmation is requested or required.

`start [-t tray-number] pathname . . .`

Spin up the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

`-t` Spin up all disks in the tray specified by *tray-number*. *pathname* must specify the SPARCstorage Array controller.

`stop [-t tray-number] pathname . . .`

Spin down the specified disk(s). If *pathname* specifies the SPARCstorage Array controller, this action applies to all disks in the SPARCstorage Array.

`-t` Spin down all disks in the tray specified by *tray-number*. *pathname* must specify the SPARCstorage Array controller.

SPARCstorage Array Subcommands

`fast_write [-s] -c pathname`

`fast_write [-s] -d pathname`

`fast_write [-s] -e pathname`

Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* refers to the SPARCstorage Array controller or to an individual disk.

`-s` Cause the SPARCstorage Array to save the change so it will persist across power-cycles.

`-c` Enable fast writes for synchronous writes only.

`-d` Disable fast writes.

`-e` Enable fast writes.

`nvrाम_data pathname`

Display the amount of fast write data in the NVRAM for the specified disk. This command can only be used for an individual disk.

`perf_statistics -d pathname`

`perf_statistics -e pathname`

Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be enabled before using the display `-p` subcommand. This subcommand can be issued only to the SPARCstorage Array controller.

`-d` Disable the accumulation of performance statistics.

luxadm(1M)

	<p>-e Enable the accumulation of performance statistics.</p> <p>purge <i>pathname</i> Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.</p> <p>sync_cache <i>pathname</i> Flush all outstanding writes for the specified disk from NVRAM to the media. If <i>pathname</i> specifies the controller, this action applies to all disks in the SPARCstorage Array subsystem.</p>
Enclosure Services Card Subcommands	<p>The <i>env_display</i> and <i>alarm*</i> subcommands apply only to an Enclosure Services Card (SES) in a RSM tray in a SPARCstorage Array. The RSM tray is addressed by using the logical or physical path of the SES device or by specifying the controller followed by the tray number. The controller is addressed by <i>cN</i> or the physical path to the SSA's controller.</p> <p><i>alarm pathname controller tray_number</i> Display the current state of audible alarm.</p> <p><i>alarm_off pathname controller tray_number</i> Disable the audible alarm for this RSM tray.</p> <p><i>alarm_on pathname controller tray_number</i> Enable the audible alarm for this RSM tray.</p> <p><i>alarm_set controller-pathname controller tray_number [seconds]</i> Set the audible alarm setting to seconds.</p> <p><i>env_display pathname controller tray_number</i> Display the environmental information for the specified unit.</p>
SENA, Sun Fire 880 Internal Storage Subsystem, and Individual FC_AL Drive Expert Mode Subcommands	<p>The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.</p> <p>If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.</p> <p>-e <i>forcelip enclosure[, dev] ... pathname ...</i> Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or <i>pathname</i> can specify any device on the loop. Use the <i>pathname</i> to specify a specific path for multiple loop configurations.</p> <p>This is an expert only command and should be used with caution. It will reset all ports on the loop.</p>

**Other Expert Mode
Subcommands**

`-e rdls enclosure[, dev] ... | pathname ...`

Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

See NOTES for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.

These commands do not apply to the Sun Fire 880 internal storage subsystem.

`-e bus_getstate pathname`

Get and display the state of the specified bus.

`-e bus_quiesce pathname`

Quiesce the specified bus.

`-e bus_reset pathname`

Reset the specified bus only.

`-e bus_resetall pathname`

Reset the specified bus and all devices.

`-e bus_unquiesce pathname`

Unquiesce the specified bus, the specified device.

`-e dev_getstate pathname`

Get and display the state of the specified device.

`-e dev_reset pathname`

Reset the specified device.

`-e offline pathname`

Take the specified device offline.

`-e online pathname`

Put the specified device online.

EXAMPLES

EXAMPLE 1 Displaying the SENAs and Individual FC_AL Devices on a System

The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

```
example% luxadm probe
```

EXAMPLE 2 Displaying an SSA

The following example displays an SSA:

```
example% luxadm display c1
```

EXAMPLE 3 Displaying a SENA or Sun Fire 880 Internal Storage Subsystem

The following example displays a SENA or Sun Fire 880 internal storage subsystem:

```
example% luxadm display /dev/es/ses0
```

EXAMPLE 3 Displaying a SENA or Sun Fire 880 Internal Storage Subsystem (Continued)

EXAMPLE 4 Displaying Two Subsystems

The following example displays two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

EXAMPLE 5 Displaying Information about the First Disk

The following example displays information about the first disk in the front of the enclosure named BOB . Use `f` to specify the front disks. Use `r` to specify the rear disks.

```
example% luxadm display BOB,f0
```

EXAMPLE 6 Displaying Information on a Sun Fire 880 Internal Storage Subsystem

The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use `s` to specify the slot:

```
example% luxadm display BOB,s0
```

EXAMPLE 7 Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive

The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of 2200002037001246:

```
example% luxadm display 2200002037001246
```

EXAMPLE 8 Using Unique Characters to Issue a Subcommand

The following example uses only as many characters as are required to uniquely identify a subcommand:

```
example% luxadm disp BOB
```

EXAMPLE 9 Displaying Error Information

The following example displays error information about the loop that the enclosure BOB is on:

```
example% luxadm display -r BOB
```

EXAMPLE 10 Downloading New Firmware into the Interface Board

The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):

```
example% luxadm download -s BOB
```

EXAMPLE 10 Downloading New Firmware into the Interface Board (Continued)

EXAMPLE 11 Displaying Information from the SCSI Inquiry Command

The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

```
example% luxadm inq /dev/rdisk/c?t?d?s2
```

EXAMPLE 12 Hotplugging

The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB :

```
example% luxadm insert_device BOB,f0
```

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:

```
example% luxadm insert_device SF880-1,s0
```

EXAMPLE 13 Running an Expert Subcommand

The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

```
example% luxadm -e forcelp BOB
```

EXAMPLE 14 Using the Expert Mode Hot Plugging Subcommands

An example of using the expert mode hot plugging subcommands to hot remove a disk on a SSA follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdisk/c1t8d0s2
```

EXAMPLE 15 Taking the Disk to be Removed Offline

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# luxadm -e offline /dev/rdisk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdisk/c1t8d0s2
```

EXAMPLE 16 Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

luxadm(1M)

EXAMPLE 16 Unquiescing the Bus *(Continued)*

```
example# luxadm -e bus_unquiesce /dev/rdisk/c1t8d0s2
example# luxadm -e online /dev/rdisk/c1t8d0s2
example# luxadm release /dev/rdisk/c1t8d0s2
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `LANG` environment variable that affects the execution of `luxadm`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
-1 An error occurred.

FILES

`usr/lib/firmware/fc_s/fc_s_fcode`
`usr/lib/firmware/ssa/ssafirmware`
`usr/lib/locale/C/LC_MESSAGES/ibfirmware`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

RAID Manager 6.1 Installation and Support Guide Answerbook
RAID Manager 6.1 User's Guide Answerbook

NOTES

See the *SENA Array Installation and Service Manual* for additional information on the SENA. Refer to *Tutorial for SCSI use of IEEE Company_ID*, R. Snively, for additional information regarding the IEEE extended WWN. See `SEE ALSO`. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

will be displayed.

You must be careful not to quiesce a bus that contains the root or the `/usr` filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.

NAME	m64config, SUNWm64_config – configure the M64 Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/m64config [-defaults] [-depth 8 24 32] [-dev device-filename] [-file machine system] [-prconf] [-propt] [-res video-mode [now try] [noconfirm nocheck]] /usr/sbin/m64config [-prconf] [-propt] /usr/sbin/m64config [-help] [-res ?] </pre>
DESCRIPTION	<p>m64config configures the M64 Graphics Accelerator and some of the X11 window system defaults for M64.</p> <p>The first form of m64config stores the specified options in the OWconfig file. These options will be used to initialize the M64 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The second and third forms which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.</p> <p>Options may be specified for only one M64 device at a time. Specifying options for multiple M64 devices requires multiple invocations of m64config.</p> <p>Only M64-specific options can be specified through m64config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the <i>OpenWindows Desktop Reference Manual</i> for details.</p> <p>The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.</p> <p>Both of these standard OWconfig files can only be written by root. Consequently, the m64config program, which is owned by the root user, always runs with setuid root permission.</p>
OPTIONS	<p>-defaults Resets all option values to their default values.</p> <p>-depth 8 24 32 Sets the depth (bits per pixel) on the device. Possible values are 8, 24, or 32 (where 32 uses 24 bits per pixel). Log out of the current window system session and log back in for the change to take effect. 24 or 32 enables TrueColor graphics in the window system, at the expense of screen resolution.</p> <p>The 32 setting enables simultaneous 8- and 24-bit color windows on m64 devices that support it. With setting 32, -propt shows depth 32 and -prconf shows</p>

m64config(1M)

depth 24. To check window depth, use the `xwininfo` utility. The `xwininfo` utility is usually shipped in the package containing frame buffer software (such as `SUNWxwplt`).

The maximum resolution that is available with 24 bits per pixel depends on the amount of memory installed on the PGX card. For 2-MB PGX cards, the maximum available resolution is 800x600. For 4-MB cards, it is 1152x900. For 8-MB cards, it is 1920x1080. If there is not enough memory for the specified combination of resolution and depth, `m64config` displays an error message and exits.

-dev *device-filename*

Specifies the M64 special file. If not specified, `m64config` will try `/dev/fbs/m640` through `/dev/fbs/m648` until one is found.

-file *machine|system*

Specifies which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

-help

Prints a list of the `m64config` command line options, along with a brief explanation of each.

-prconf

Prints the M64 hardware configuration. The following is a typical display using the `-prconf` option:

```
--- Hardware Configuration for /dev/fbs/m640 ---
ASIC: version 0x41004754
DAC: version 0x0
PROM: version 0x0
Card possible resolutions: 640x480x60, 800x600x75, 1024x768x60
1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76
1280x1024x60, 1152x900x66, 1152x900x76, 1280x1024x67
960x680x112S, 960x680x108S, 640x480x60i, 768x575x50i, 1280x800x76
1440x900x76, 1600x1000x66, 1600x1000x76, vga, svga, 1152, 1280
stereo, ntsc, pal
Monitor possible resolutions: 720x400x70, 720x400x88, 640x480x60
640x480x67, 640x480x72, 640x480x75, 800x600x56, 800x600x60

1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76, 1152x900x66
1152x900x76, 1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
stereo
Possible depths: 8, 24
Current resolution setting: 1280x1024x76
Current depth: 8
```

-propt

Prints the current values of all M64 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of

options as they will be in the OWconfig file after the call to `m64config` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/m640 ---
OWconfig: machine
Video Mode: not set
Depth: 8
```

`-res video-mode [now | try [noconfirm | nocheck]]`

Specifies the video mode used to drive the monitor connected to the specified M64 device. Video modes are built-in. *video-mode* has the format of *widthxheightxrate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` preceding the refresh rate instead of `x`. For example, `1280x1024@76`.

A list of valid video modes is obtained by issuing the following command: `m64config -res '?'`. Note that the `?` must be quoted. Not all resolutions are supported by both the video board and by the monitor. `m64config` will not permit you to set a resolution the board does not support, and will request confirmation before setting a resolution the monitor does not support.

Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

Name	Corresponding Video Mode
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
none	(video mode currently programmed in device)

The `-res` option also accepts additional sub-options immediately following the video mode specification. Any or all of these may be present.

`nocheck` If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the M64 device. *Use of this option implies noconfirm as well.*

m64config(1M)

- noconfirm** Using the `-res` option, the user could potentially put the system into an usable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `m64config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `m64config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `m64config` is being run from a shell script.
- now** If present, not only will the video mode be updated in the `OWconfig` file, but the M64 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).
- It is inadvisable to use this sub-option with `m64config` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `m64config` with the `now` sub-option, first bring the window system down. If the `now` sub-option is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and reentered again. Consequently, this usage is strongly discouraged.
- try** If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `'y'` or carriage return is considered a no and the previous video mode will be restored and `m64config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` sub-option. (See the warning note on the `now` sub-option).

DEFAULTS For a given invocation of `m64config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an M64 option has never been specified by `m64config`, a default value is used. The option defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fbs/m640</code>

-file	machine
-res	none

The default for the `-res` option of `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default M64 video mode.

EXAMPLES **EXAMPLE 1** Switching the Monitor Type

The following example switches the monitor type to the maximum resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/m64config -res 1280x1024x76
```

FILES

- /dev/fbs/m640
device special file
- /etc/openwin/server/etc/OWconfig
system config file
- /usr/lib/fbconfig/SUNWm64_config

mail.local(1M)

NAME	mail.local – store mail in a mailbox
SYNOPSIS	<code>/usr/lib/mail.local [-f sender] [-d] recipient</code>
DESCRIPTION	<p>mail.local reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by sendmail(1M) as a mail delivery agent for local mail. It is not a user interface agent.</p> <p>Messages are appended to the user's mail file in the <code>/var/mail</code> directory. The user must be a valid user name.</p> <p>Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:</p> <pre>From sender_address time_stamp</pre> <p>The <i>sender_address</i> is extracted from the SMTP envelope address (the envelope address is specified with the <code>-f</code> option).</p> <p>A trailing blank line is also added to the end of each message.</p> <p>The mail files are locked with a <code>.lock</code> file while mail is appended.</p> <p>The mail files are created with mode <code>660</code>, owner is set to <i>recipient</i>, and group is set to <code>mail</code>. If the "biff" service is returned by <code>getservbyname(3SOCKET)</code>, the biff server is notified of delivered mail. This program also computes the <code>Content-Length:</code> header which will be used by the mailbox reader to mark the message boundary.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-f sender</code> Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.<code>-d</code> Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, <code>mail.local recipient</code> is the same as <code>mail.local -d recipient</code>.<code>-l</code> Turn on LMTP mode.<code>-r from</code> Specify the sender's name (for backward compatibility).<code>-7</code> Do not advertise 8BITMIME support in LMTP mode.<code>-b</code> Return a permanent error instead of a temporary error if a mailbox exceeds quota.
OPERANDS	<p>The following operand is supported:</p> <ul style="list-style-type: none"><i>recipient</i> The recipient of the mail message.
ENVIRONMENT VARIABLES	<p><code>TZ</code> Used to set the appropriate time zone on the timestamp.</p>
EXIT STATUS	<p>The following exit values are returned:</p>

0 Successful operation.

>0 An error occurred.

FILES /tmp/local.XXXXXXX temporary files
 /tmp/lochd.XXXXXXX temporary files
 /var/mail/*user_name* user's mail file

makedbm(1M)

NAME	makedbm – make a dbm file, or get a text file from a dbm file
SYNOPSIS	makedbm [-b] [-l] [-s] [-E] [-i <i>yp_input_file</i>] [-o <i>yp_output_name</i>] [-d <i>yp_domain_name</i>] [-m <i>yp_master_name</i>] [-S <i>delimiter</i>] [-D <i>number_of_delimiters</i>] <i>infile outfile</i> makedbm [-u <i>dbmfilename</i>]
DESCRIPTION	<p>The makedbm utility takes the <i>infile</i> and converts it to a pair of files in ndbm format (see <code>dbm_clearerr(3C)</code>), namely <i>outfile.pag</i> and <i>outfile.dir</i>. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with '\ ' (backslash), the data for that record is continued on to the next line. makedbm does not treat '#' (pound-sign) as a special character.</p> <p>Because makedbm is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key <i>yp_last_modified</i>, which is the date of <i>infile</i> (or the current time, if <i>infile</i> is '-'). The entries that have keys with the prefix <i>yp_</i> are interpreted by NIS server utilities.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-b Insert the YP_INTERDOMAIN into the output. This key causes <code>ypserv(1M)</code> to use DNS for host name and address lookups for hosts not found in the maps.-d <i>yp_domain_name</i> Create a special entry with the key <i>yp_domain_name</i>.-D <i>number_of_delimiters</i> Specify <i>number_of_delimiters</i> to skip before forming the key.-E Delimiters are escaped.-i <i>yp_input_file</i> Create a special entry with the key <i>yp_input_file</i>.-l Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.-m <i>yp_master_name</i> Create a special entry with the key <i>yp_master_name</i>. If no master host name is specified, <i>yp_master_name</i> is set to the local host name.-o <i>yp_output_name</i> Create a special entry with the key <i>yp_output_name</i>.-s Secure map. Accept connections from secure NIS networks only.-S <i>delimiter</i> Specify the <i>delimiter</i> to use instead of the default delimiter for forming the key.-u <i>dbmfilename</i> Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from

values.

OPERANDS The following operands are supported:

infile Input file for makedbm. If *infile* is '-' (dash), the standard input is read.

outfile One of two output files in ndbm format: *outfile.pag* and *outfile.dir*.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

makemap(1M)

NAME	makemap – create database maps for sendmail
SYNOPSIS	makemap [-N] [-d] [-f] [-o] [-r] [-s] [-v] [-C <i>file</i>] [-c <i>cache</i> size] [-e] [-l] [-u] <i>map</i> type <i>map</i> name
DESCRIPTION	<p>makemap creates the database maps used by the keyed map lookups in sendmail(1M). makemap reads from the standard input and outputs to the specified <i>mapname</i>.</p> <p>In all cases, makemap reads lines from the standard input consisting of two words separated by white space. The first is the database key, the second is the value. The value may contain %<i>n</i> strings to indicated parameter substitution. Literal percents should be doubled (%%). Blank lines and lines beginning with # are ignored.</p> <p>makemap handles three different database formats. Database format is selected using the <i>map</i>type parameter. See OPERANDS.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-C Use the specified sendmail configuration file for looking up the TrustedUser option.-N Include the null byte that terminates strings in the map. This must match the -N flag in the K line in <code>sendmail.cf</code>-c Use the specified hash and B-Tree cache size.-d Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, they will both be inserted into the map.-e Allow empty value (right hand side).-f Normally all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the -f flag in the K line in <code>sendmail.cf</code>. The value is never case folded.-l List supported map types.-o Append to an old file. This allows you to augment an existing file.-r Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.-s Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.-u Dump (unmap) the content of the database to standard output.-v Verbosely print what it is doing.
OPERANDS	<p>The following operands are supported:</p> <p><i>mapname</i> File name of the database map being created.</p>

maptypes Specifies the database format. The following *maptypes* parameters are available:

dbm Specifies DBM format maps.

btree Specifies B-Tree format maps.

hash Specifies hash format maps.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

mib2mof(1M)

NAME	mib2mof – generate MOF file(s) from input SNMP MIB file(s)																																																																								
SYNOPSIS	<code>/usr/sadm/bin/mib2mof [-n] [-d <i>directory</i>] [-q] [-c] [-a] [-h] <i>files</i></code>																																																																								
DESCRIPTION	<p>The <code>mib2mof</code> utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.</p> <p>SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:</p> <ul style="list-style-type: none"> ■ syntax ■ read/write access ■ OID (Object Identifier) ■ description (optional) ■ index (if the variable is within a group [sequence] that defines a row) <p>The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).</p> <p>The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:</p> <table border="0"> <thead> <tr> <th>SNMP SMI Datatype</th> <th>SNMP Ver.</th> <th>CIM Datatype</th> <th>SNMP API Object type</th> </tr> </thead> <tbody> <tr> <td>INTEGER</td> <td>v1</td> <td>sint32</td> <td>SnmpInt</td> </tr> <tr> <td>OCTET STRING</td> <td>v1</td> <td>string</td> <td>SnmpString</td> </tr> <tr> <td>OBJECT IDENTIFIER</td> <td>v1</td> <td>string</td> <td>SnmpOid</td> </tr> <tr> <td>IpAddress</td> <td>v1</td> <td>string</td> <td>SnmpIpAddress</td> </tr> <tr> <td>Counter</td> <td>v1</td> <td>uint32</td> <td>SnmpCounter</td> </tr> <tr> <td>Gauge</td> <td>v1</td> <td>uint32</td> <td>SnmpGauge</td> </tr> <tr> <td>TimeTicks</td> <td>v1</td> <td>uint32</td> <td>SnmpTimeticks</td> </tr> <tr> <td>Opaque</td> <td>v1</td> <td>sint8 []</td> <td>SnmpOpaque</td> </tr> <tr> <td>DisplayString - see OCTET STRING</td> <td>v1</td> <td></td> <td></td> </tr> <tr> <td>NetworkAddress - see IpAddress</td> <td>v1</td> <td></td> <td></td> </tr> <tr> <td>Counter32 - see Counter</td> <td>v2</td> <td></td> <td></td> </tr> <tr> <td>Counter64</td> <td>v2</td> <td>uint64</td> <td>SnmpCounter64</td> </tr> <tr> <td>Integer32</td> <td>v2</td> <td>sint32</td> <td>SnmpInt</td> </tr> <tr> <td>Gauge32 - see Gauge</td> <td>v2</td> <td></td> <td></td> </tr> <tr> <td>Unsigned32</td> <td>v2</td> <td>uint32</td> <td>SnmpGauge</td> </tr> <tr> <td>TruthValue</td> <td>v2</td> <td>sint32</td> <td>SnmpInt</td> </tr> <tr> <td>BITS - see OCTET STRING</td> <td>v2</td> <td></td> <td></td> </tr> </tbody> </table> <p>The <code>mib2mof</code> utility includes its required <code>Solaris_SNMPmib_core.txt</code> file (containing core MIB definitions), installed in <code>/usr/sadm/mof</code>. The <code>mib2mof</code> utility looks first for <code>mib</code> core file in local directory. If this file is not found in the local directory, <code>mib2mof</code> looks in <code>/usr/sadm/mof</code>.</p>	SNMP SMI Datatype	SNMP Ver. BITS - see OCTET STRING	v2																																																																								

A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the `Solaris_SNMPmib_core.txt` file.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name (and CIM class) is of the format `<SNMP_><MIB name><Group name>.mof`.

OPTIONS The following options are supported:

- a Generate MOF files for all of the input MIB files. If -a is not given, a MOF file is generated only for the last file of the input list.
- c Do not use the default `Solaris_SNMPmib_core.txt` definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another `MIB_CORE` definitions file as one of the input files.
- d *directory* Generate output MOF files in the specified directory.
- h Show how to invoke `mib2mof` and list its arguments.
- n Parse the input MIB files without generating any output.
- q Include the `DESCRIPTION` clause of `SNMP OBJECT-TYPE` as a qualifier in the generated MOF file.

OPERANDS The following operands are supported:

files List of SNMP MIB files to be converted.

EXIT STATUS The `mib2mof` utility terminates with exit status 0.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbcou

mibiisa(1M)

NAME	mibiisa – Sun SNMP Agent
SYNOPSIS	mibiisa [-ar] [-c <i>config-dir</i>] [-d <i>debug-level</i>] [-p <i>port</i>] [-t <i>cache-timer</i>]
DESCRIPTION	<p>The <i>mibiisa</i> utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in <i>RFC 1213</i>, with Sun extensions under Sun's enterprise number. The MIB (Management Information Base) is both readable and writable. The <i>mibiisa</i> utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.</p> <p>The <i>mibiisa</i> utility supports the coldStart, linkUp, linkDown, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.</p> <p>The <i>mibiisa</i> utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.</p> <p>To enhance security, <i>mibiisa</i> supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the <i>mibiisa</i>. See the SECURITY section for more information.</p> <p>Unless overridden, <i>mibiisa</i> uses UDP port 161, the standard SNMP port. The <i>mibiisa</i> utility issues traps through the same port on which it receives SNMP requests.</p> <p>The <i>mibiisa</i> utility must run with super-user privileges and is typically started at system startup via <i>/etc/rc3.d</i>. <i>mibiisa</i> may not be started using <i>inetd(1M)</i>. When started, <i>mibiisa</i> detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and SIGUSR2, and places itself in the background.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Disable the generation of authentication traps. However, an SNMP manager may write a value into <code>snmpEnableAuthenTraps</code> to enable or disable authentication traps.-c <i>config-dir</i> Specify a directory where it expects <code>snmpd.conf</code> file, on startup. The default directory is <code>/etc/snmp/conf</code>.-d <i>debug-level</i> Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When <i>mibiisa</i> receives the signal SIGUSR1, it resets the debug-level to 0. When <i>mibiisa</i> receives the signal SIGUSR2, it increments the debug-level by one. <p>Debug output is sent to the standard output in effect at the time <i>mibiisa</i> is started. No matter what debug level is in effect, certain significant events are logged in the system log.</p>

**CONFIGURATION
FILE**

- p *port* Define an alternative UDP port on which mibiisa listens for incoming requests. The default is UDP port 161.
- r Place the MIB into read-only mode.
- t *cache-timer* By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set *cache-timer* to any value less than 1.

The `snmpd.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

- `sysdescr` The value to be used to answer queries for `sysDescr`.
- `syscontact` The value to be used to answer queries for `sysContact`.
- `syslocation` The value to be used to answer queries for `sysLocation`.
- `trap` The parameter names one or more hosts to receive traps. Only five hosts may be listed.
- `system-group-read-community` The community name to get read access to the system group and Sun's extended system group.
- `system-group-write-community` The community name to get write access to the system group and Sun's extended system group.
- `read-community` The community name to get read access to the entire MIB.
- `write-community` The community name to get write access to the entire MIB (implies read access).
- `trap-community` The community name to be used in traps.
- `kernel-file` The name of the file to use for kernel symbols.
- `managers` The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.

mibiisa(1M)

newdevice

The additional devices which are not built in SNMPD. The format is as follows:
newdevice *type* *speed* *name* where *newdevice* is the keyword, *type* is an integer which has to match your schema file, *speed* is the new device's speed, and *name* is this new device's name.

An example `snmpd.conf` file is shown below:

```
sysdescr      Sun SNMP Agent, SPARCstation 10, Company
              Property Number 123456
syscontact    Cliff Claven
sysLocation   Stool next to Norms at Cheers
#
system-group-read-community    public
system-group-write-community   private
#
read-community  all_public
write-community all_private
#
trap            localhost
trap-community  SNMP-trap
#
#kernel-file    /vmunix
#
managers        lvs golden
managers        swap
```

INSTALLATION

The `mibiisa` utility and its configuration file, `snmpd.conf`, may be placed in any directory. However for Solaris 2.4 and subsequent releases, use `/usr/lib/snmp` for `mibiisa` itself and `/etc/snmp/conf` for the configuration file. You can modify the configuration file as appropriate. If you make any changes to `snmpd.conf` file keyword values, you must kill and restart `mibiisa` for the changes to take effect.

Your `/etc/services` file (or NIS equivalent) should contain the following entries:

snmp	161/udp		# Simple Network Mgmt Protocol
snmp-trap	162/udp	snmptrap	# SNMP trap (event) messages

The following is an example for Solaris 2.x:

```
#
# Start the SNMP agent
#
if [ -f /etc/snmp/conf/snmpd.conf -a -x
    /usr/lib/snmp/mibiisa ];
then
```

```
/opt/SUNWconn/snm/agents/snmpd
echo 'Starting SNMP-agent.'
```

SECURITY

SNMP, as presently defined, offers relatively little security. The `mibiisa` utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which `mibiisa` will accept requests. If you do not specify any such manager stations, `mibiisa` accepts requests from anywhere.

The `mibiisa` utility also allows you to mark the MIB as “read-only” by using the `-r` option.

Finally, `mibiisa` supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```
-rw----- 1 root          2090 Oct 17 15:04 /etc/snm/conf/snmpd.conf
```

MIB

This section discusses some of the differences between the `mibiisa` MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the `mibiisa` MIB:

```
sysName
atIfIndex
ipDefaultTTL
```

These variables are read-write in the standard MIB-II.

The `mibiisa` MIB Address Translation tables support limited write access: only `atPhysAddress` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The `mibiisa` MIB IP Net to Media table supports limited write access: only `ipNetToMediaPhysAddress` and `ipNetToMediaType` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the `mibiisa` MIB; however, these variables have fixed values. Any new values “set” to them are accepted, but have no effect:

```
ipRouteIfIndex
ipRouteMetric1
ipRouteMetric2
ipRouteMetric3
ipRouteMetric4
ipRouteType
```

mibiisa(1M)

ipRouteAge
ipRouteMask
ipRouteMetric5

The following mibiisa MIB variable reflects the actual state of the related table entry. "Sets" are accepted but have no effect:

tcpConnState

The following mibiisa MIB variables are readable, but return a fixed value:

icmpInDestUnreachs	Returns 1
icmpInTimeExcds	Returns 1
icmpInParmProbs	Returns 1
icmpInSrcQuenchs	Returns 1
icmpInRedirects	Returns 1
icmpInEchos	Returns 1
icmpInEchoReps	Returns 1
icmpInTimestamps	Returns 1
icmpInTimestampReps	Returns 1
icmpInAddrMasks	Returns 1
icmpInAddrMaskReps	Returns 1
icmpOutDestUnreachs	Returns 1
icmpOutTimeExcds	Returns 1
icmpOutParmProbs	Returns 1
icmpOutSrcQuenchs	Returns 1
icmpOutRedirects	Returns 1
icmpOutEchos	Returns 1
icmpOutEchoReps	Returns 1
icmpOutTimestamps	Returns 1
icmpOutTimestampReps	Returns 1
icmpOutAddrMasks	Returns 1
icmpOutAddrMaskReps	Returns 1

ifInUnknownProtos	Returns 0
ipAdEntBcastAddr	Returns 1
ipAdEntReasmMaxSiz	Returns 65535
ipRouteMetric1	Returns -1
ipRouteMetric2	Returns -1
ipRouteMetric3	Returns -1
ipRouteMetric4	Returns -1
ipRouteAge	Returns 0
ipRouteMetric5	Returns -1
ipNetToMediaType	Returns (3) dynamic
ipRoutingDiscards	Returns 0

The following variables return a fixed value of 0 for drivers not conforming to the GLD framework (see `gld(7D)`), including the old LAN drivers on SPARC machines:

ifInOctets	Returns 0
ifInNUcastPkts	Returns 0
ifInDiscards	Returns 0
ifOutOctets	Returns 0
ifOutNUcastPkts	Returns 0
ifOutDiscards	Returns 0

SCHEMA ATTRIBUTES

The following describes the attributes in the group and table definitions in the `/var/snmp/mib/sun.mib` file.

system

The `system` group reports statistics about a particular system (for example, a workstation or a printer).

`sysDescr` – A textual description of the entity. This value should include the full name and version identification of the system's hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

`sysObjectID` – The vendor's authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor "Flintstones, Inc."

mibiisa(1M)

was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its "Fred Router." (objectid)

`sysUpTime` – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

`sysContact` – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

`sysName` – An administratively-assigned name for this managed node. By convention, this is the node's fully-qualified domain name. (string[255])

`sysLocation` – The physical location of this node (for example, "telephone closet, 3rd floor" (string[255]))

`sysServices` – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4 ($2^{(3-1)}$). In contrast, a node that is a host offering application services would have a value of 72 ($2^{(4-1)} + 2^{(7-1)}$). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

layer	functionality
1	physical (such as repeaters)
2	datalink/subnetwork (such as bridges)
3	internet (such as IP gateways)
4	end-to-end (such as IP hosts)
7	applications (such as mail relays)

For systems including OSI protocols, Layers 5 and 6 may also be counted.

interfaces The `interfaces` group reports the number of interfaces handled by the agent.

`ifNumber` – The number of network interfaces, regardless of their current state, present on this system. (int)

ifTable The `ifTable` is a table of interface entries. The number of entries is given by the value of `ifNumber`.

`ifIndex` – A unique value for each interface. Its value ranges between 1 and the value of `ifNumber`. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)

`ifDescr` – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])

`ifType` – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)

`ifMtu` – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)

`ifSpeed` – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)

`ifPhysAddress` – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])

`ifAdminStatus` – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`ifOperStatus` – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`ifLastChange` – The value of `sysUpTime` at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

`ifInOctets` – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifInUcastPkts` – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

`ifInNUcastPkts` – The number of non-unicast (that is, subnetwork- broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

`ifInDiscards` – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifInErrors` – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

mibiisa(1M)

`ifInUnknownPkts` – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

`ifOutOctets` – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifOutUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

`ifOutNUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a non-unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

`ifOutDiscards` – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifOutErrors` – The number of outbound packets that could not be transmitted because of errors. (counter)

`ifOutQLen` – The length of the output packet queue (in packets). (gauge)

`ifSpecific` – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

atTable `atTable` Address Translation tables contain the `NetworkAddress` to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

`atIfIndex` – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`atPhysAddress` – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invalidating the corresponding entry in the `atTable` object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular

information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `atPhysAddress` object.

`atNetAddress` – The `NetworkAddress` (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

ip The `ip` group reports statistics about the Internet Protocol (IP) group.

`ipForwarding` – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not— except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to change this object to an inappropriate value.

`ipDefaultTTL` – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

`ipInReceives` – The total number of input datagrams received from interfaces, including those received in error. (counter)

`ipInHdrErrors` – The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

`ipInAddrErrors` – The number of input datagrams discarded because the IP address in their IP header’s destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

`ipForwDatagrams` – The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source-Route option processing was successful. (counter)

`ipInUnknownProtos` – The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

`ipInDiscards` – The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for

mibiisa(1M)

example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

`ipInDelivers` – The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

`ipOutRequests` – The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in `ipForwDatagrams`. (counter)

`ipOutDiscards` – The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in `ipForwDatagrams` if any such packets met this (discretionary) discard criterion. (counter)

`ipOutNoRoutes` – The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in `ipForwDatagrams` which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

`ipReasmTimeout` – The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

`ipReasmReqds` – The number of IP fragments received that needed to be reassembled at this entity. (counter)

`ipReasmOKs` – The number of IP datagrams successfully reassembled. (counter)

`ipReasmFails` – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

`ipFragOKs` – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

`ipFragFails` – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their “Don’t Fragment” flag was set. (counter)

`ipFragCreates` – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

`ipRoutingDiscards` – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

ipAddrTable	<p><code>ipAddrTable</code> is a table of addressing information relevant to this entity's IP addresses.</p> <p><code>ipAdEntAddr</code> – The IP address to which this entry's addressing information pertains. (netaddress)</p> <p><code>ipAdEntIfIndex</code> – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of <code>ifIndex</code>. (int)</p> <p><code>ipAdEntNetMask</code> – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)</p> <p><code>ipAdEntBcastAddr</code> – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.</p> <p><code>ipAdEntReasmMaxSize</code> – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.</p>
ipRouteTable	<p>The <code>ipRouteTable</code> is this entity's IP Routing table.</p> <p><code>ipRouteDest</code> – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but access to such multiple entries is dependent on the table- access mechanisms defined by the network management protocol in use. (netaddress)</p> <p><code>ipRouteIfIndex</code> – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of <code>ifIndex</code>. (int)</p> <p><code>ipRouteMetric1</code> – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's <code>ipRouteProto</code> value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.</p> <p><code>ipRouteMetric2</code> – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's <code>ipRouteProto</code> value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.</p>

`ipRouteMetric3` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteMetric4` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteNextHop` – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent's IP address on that interface.) (netaddress)

`ipRouteType` – The type of route. Note that the values `direct` (3) and `indirect` (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value `invalid` (2) has the effect of invalidating the corresponding entry in the `ipRouteTable` object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `ipRouteType` object.

`ipRouteProto` – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of "too old" can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.

`ipRouteMask` – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the `ipRouteDest` field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the `ipRouteMask` by determining whether the value of the correspondent `ipRouteDest` field belongs to a class-A, B, or C network, and then using one of:

mask	network
255.0.0.0	class-A
255.255.0.0	class-B
255.255.255.0	class-C

	<p>If the value of the <code>ipRouteDest</code> is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)</p>
	<p><code>ipRouteMetric5</code> – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's <code>ipRouteProto</code> value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.</p>
	<p><code>ipRouteInfo</code> – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route's <code>ipRouteProto</code> value. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)</p>
ipNetToMediaTable	<p>The <code>ipNetToMediaTable</code> is the IP Address Translation table used for mapping from IP addresses to physical addresses.</p> <p><code>ipNetToMediaIfIndex</code> – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of <code>ifIndex</code>. (int)</p> <p><code>ipNetToMediaPhysAddress</code> – The media-dependent physical address. (octet[128])</p> <p><code>ipNetToMediaNetAddress</code> – The <code>IpAddress</code> corresponding to the media-dependent physical address. (netaddress)</p> <p><code>ipNetToMediaType</code> – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the <code>ipNetToMediaTable</code>. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant <code>ipNetToMediaType</code> object.</p>
icmp	<p>The <code>icmp</code> group reports statistics about the ICMP group.</p> <p><code>icmpInMsgs</code> – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by <code>icmpInErrors</code>. (counter)</p> <p><code>icmpInErrors</code> – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)</p> <p><code>icmpInDestUnreachs</code> – The number of ICMP Destination Unreachable messages received. (counter)</p>

mibiisa(1M)

`icmpInTimeExcds` – The number of ICMP Time Exceeded messages received. (counter)

`icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)

`icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)

`icmpInRedirects` – The number of ICMP Redirect messages received. (counter)

`icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)

`icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)

`icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)

`icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)

`icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)

`icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)

`icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by `icmpOutErrors`. (counter)

`icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

`icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)

`icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)

`icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)

`icmpOutSrcQuenchs` – The number of ICMP Source Quench messages sent. (counter)

`icmpOutRedirects` – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

`icmpOutEchos` – The number of ICMP Echo (request) messages sent. (counter)

`icmpOutEchoReps` – The number of ICMP Echo Reply messages sent. (counter)

`icmpOutTimestamps` – The number of ICMP Timestamp (request) messages sent. (counter)

`icmpOutTimestampReps` – The number of ICMP Timestamp Reply messages sent. (counter)

`icmpOutAddrMasks` – The number of ICMP Address Mask Request messages sent. (counter)

`icmpOutAddrMaskReps` – The number of ICMP Address Mask Reply messages sent. (counter)

tcp The `tcp` group reports statistics about the TCP group.

`tcpRtoAlgorithm` – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)

`tcpRtoMin` – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is `rsre(3)`, an object of this type has the semantics of the `LBOUND` quantity described in RFC 793. (int)

`tcpRtoMax` – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is `rsre(3)`, an object of this type has the semantics of the `UBOUND` quantity described in RFC 793. (int)

`tcpMaxConn` – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value `-1`. (int)

`tcpActiveOpens` – The number of times that TCP connections have made a direct transition to the `SYN-SENT` state from the `CLOSED` state. (counter)

`tcpPassiveOpens` – The number of times that TCP connections have made a direct transition to the `SYN-RCVD` state from the `LISTEN` state. (counter)

`tcpAttemptFails` – The number of times that TCP connections have made a direct transition to the `CLOSED` state from either the `SYN-SENT` state or the `SYN-RCVD` state, plus the number of times TCP connections have made a direct transition to the `LISTEN` state from the `SYN-RCVD` state. (counter)

`tcpEstabResets` – The number of times TCP connections have made a direct transition to the `CLOSED` state from either the `ESTABLISHED` state or the `CLOSE-WAIT` state. (counter)

mibiisa(1M)

	<p><code>tcpCurrEstab</code> – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)</p> <p><code>tcpInSegs</code> – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)</p> <p><code>tcpOutSegs</code> – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)</p> <p><code>tcpRetransSegs</code> – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)</p> <p><code>tcpInErrs</code> – The total number of segments received in error (for example, bad TCP checksums). (counter)</p> <p><code>tcpOutRsts</code> – The number of TCP segments sent containing the RST flag. (counter)</p>
tcpConnTable	<p>The <code>tcpConnTable</code> is a table containing TCP connection-specific information.</p> <p><code>tcpConnState</code> – The state of this TCP connection. (enum)</p> <p>The only value that may be set by a management station is <code>deleteTCB(12)</code>. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to set this object to any other value.</p> <p>If a management station sets this object to the value <code>deleteTCB(12)</code>, then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.</p> <p>As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)</p> <p><code>tcpConnLocalAddress</code> – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)</p> <p><code>tcpConnLocalPort</code> – The local port number for this TCP connection. (int)</p> <p><code>tcpConnRemAddress</code> – The remote IP address for this TCP connection. (netaddress)</p> <p><code>tcpConnRemPort</code> – The remote port number for this TCP connection. (int)</p>
udp	<p>The <code>udp</code> group reports statistics about the UDP group.</p> <p><code>udpInDatagrams</code> – The total number of UDP datagrams delivered to UDP users. (counter) Returns a fixed value of 0.</p>

	<p><code>udpNoPorts</code> – The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.</p> <p><code>udpInErrors</code> – The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)</p> <p><code>udpOutDatagrams</code> – The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.</p>
udpTable	<p>The <code>udpTable</code> is a table containing UDP listener information.</p> <p><code>udpLocalAddress</code> – The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)</p> <p><code>udpLocalPort</code> – The local port number for this UDP listener. (int)</p>
snmp	<p>The <code>snmp</code> group reports statistics about the SNMP group.</p> <p><code>snmpInPkts</code> – The total number of Messages delivered to the SNMP entity from the transport service. (counter)</p> <p><code>snmpOutPkts</code> – The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)</p> <p><code>snmpInBadVersions</code> – The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)</p> <p><code>snmpInBadCommunityNames</code> – The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)</p> <p><code>snmpInBadCommunityUses</code> – The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)</p> <p><code>snmpInASNParseErrs</code> – The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)</p> <p><code>snmpInTooBigs</code> – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)</p> <p><code>snmpInNoSuchNames</code> – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)</p> <p><code>snmpInBadValues</code> – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)</p>

`snmpInReadOnlys` – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “readOnly.” It should be noted that it is a protocol error to generate an SNMP PDU that contains the value “readOnly” in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

`snmpInGenErrs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpInTotalReqVars` – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

`snmpInTotalSetVars` – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

`snmpInGetRequests` – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetNexts` – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInSetRequests` – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetResponses` – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInTraps` – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpOutTooBig`s – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpOutNoSuchName`s – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is “noSuchName.” (counter)

`snmpOutBadValue`s – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpOutGenErrs` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpOutGetRequests` – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

`snmpOutGetNexts` – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)

`snmpOutSetRequests` – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

`snmpOutGetResponses` – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

`snmpOutTraps` – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

`snmpEnableAuthenTraps` – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

sunSystem The `sunSystem` group reports general system information.

`agentDescr` – The SNMP agent’s description of itself. (string[255])

`hostID` – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

`motd` – The first line of `/etc/motd`. (string[255])

`unixTime` – The UNIX system time. Measured in seconds since January 1, 1970 GMT. (counter)

sunProcessTable The `sunProcessTable` table reports UNIX process table information.

`psProcessID` – The process identifier for this process. (int)

`psParentProcessID` – The process identifier of this process’s parent. (int)

`psProcessSize` – The combined size of the data and stack segments (in kilobytes.) (int)

`psProcessCpuTime` – The CPU time (including both user and system time) consumed so far. (int)

`psProcessState` – The run-state of the process. (octet[4])

R	Runnable
T	Stopped
P	In page wait

mibiisa(1M)

D	Non-interruptable wait
S	Sleeping (less than 20 seconds)
I	Idle (more than 20 seconds)
Z	Zombie

psProcessWaitChannel – Reason process is waiting. (octet[16])

psProcessTTY – Terminal, if any, controlling this process. (octet[16])

psProcessUserName – Name of the user associated with this process. (octet[16])

psProcessUserID – Numeric form of the name of the user associated with this process. (int)

psProcessName – Command name used to invoke this process. (octet[64])

psProcessStatus – Setting this variable will cause a signal of the set value to be sent to the process. (int)

sunHostPerf The sunHostPerf group reports hostperf information.

rsUserProcessTime – Total number of timeticks used by user processes since the last system boot. (counter)

rsNiceModeTime – Total number of timeticks used by “nice” mode since the last system boot. (counter)

rsSystemProcessTime – Total number of timeticks used by system processes since the last system boot. (counter)

rsIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)

rsDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)

rsDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)

rsDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)

rsDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

rsVPagesIn – Number of pages read in from disk. (counter)

rsVPagesOut – Number of pages written to disk. (counter)

rsVSwapIn – Number of pages swapped in. (counter)
 rsVSwapOut – Number of pages swapped out. (counter)
 rsVIntr – Number of device interrupts. (counter)
 rsIfInPackets – Number of input packets. (counter)
 rsIfOutPackets – Number of output packets. (counter)
 rsIfInErrors – Number of input errors. (counter)
 rsIfOutErrors – Number of output errors. (counter)
 rsIfCollisions – Number of output collisions. (counter)

FILES /etc/snmp/conf/snmpd.conf configuration information
 /var/snmp/mib/sun.mib standard SNMP MIBII file

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmibii
Interface Stability	Obsolete

SEE ALSO inetd(1M), select(3C), recvfrom(3SOCKET), sendto(3SOCKET), attributes(5), gld(7D),

DIAGNOSTICS cannot dispatch request
 The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.

select(3C) failed
 A select(3C) call failed. The rest of the message indicates the cause of the failure.

sendto(3SOCKET) failed
 A sendto(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

recvfrom(3SOCKET) failed
 A recvfrom(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

no response from system
 The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.

mibiisa(1M)

response too big
The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.

missing attribute
An attribute is missing from the requested group.

bad attribute type
An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.

cannot get sysUpTime
The proxy agent cannot get the variable *sysUpTime* from the SNMP agent.

sysUpTime type bad
The variable *sysUpTime* received from the SNMP agent has the wrong data type.

unknown SNMP error
An unknown SNMP error was received.

bad variable value
The requested specified an incorrect syntax or value for a set operation.

variable is read only
The SNMP agent did not perform the set request because a variable to set may not be written.

general error
A general error was received.

cannot make request PDU
An error occurred building a request PDU.

cannot make request varbind list
An error occurred building a request variable binding list.

cannot parse response PDU
An error occurred parsing a response PDU.

request ID - response ID mismatch
The response ID does not match the request ID.

string contains non-displayable characters
A displayable string contains non-displayable characters.

cannot open schema file
An error occurred opening the proxy agent schema file.

cannot parse schema file
The proxy agent couldn't parse the proxy agent schema file.

cannot open host file
An error occurred opening the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snmpd.conf*

cannot parse host file

The proxy agent was unable to parse the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snm.conf*.

attribute unavailable for set operations

The set could not be completed because the attribute was not available for set operations.

BUGS The mibiisa utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The mibiisa utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from mibiisa contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as mibiisa is running. mibiisa does not save the changes to */etc/snmp/conf/snmpd.conf*.

mipagent(1M)

NAME	mipagent – Mobile IP agent				
SYNOPSIS	<code>/usr/lib/inet/mipagent</code>				
DESCRIPTION	<p>The <code>mipagent</code> utility implements the Mobile IP home agent and foreign agent functionality described in <i>RFC 2002, IP Mobility Support</i>. The term “mobility agent” is used to refer to the home agent and foreign agent functionality collectively. <code>mipagent</code> responds to Mobile IP registration and deregistration requests and router discovery solicitation messages from a mobile node. Besides responding to external messages, the <code>mipagent</code> utility also tasks on a periodic basis, such as aging the mobility bindings and visitor entries and sending agent advertisements. The mobility agent can also handle direct delivery style reverse tunneling as specified in <i>RFC 2344, Reverse Tunneling for Mobile IP</i>. Limited private address support for mobile nodes is also available.</p> <p>Run the <code>mipagent</code> daemon as root using the start-up script, which has the following syntax:</p> <pre>example# /etc/init.d/mipagent [start stop] /etc/inet/mipagent.conf</pre> <p>must be present before you start-up the <code>mipagent</code> daemon. See <code>mipagent.conf(4)</code>. At start up, <code>mipagent</code> reads the configuration information from <code>/etc/inet/mipagent.conf</code>. The <code>mipagent</code> daemon records a continuous log of its activities by means of <code>syslog()</code>. See <code>syslog(3C)</code>. You can use the <i>LogVerbosity</i> parameter in <code>/etc/inet/mipagent.conf</code> to control the verbosity level of the log.</p> <p>The <code>mipagent</code> daemon can be terminated either by the script:</p> <pre>example# /etc/init.d/mipagent stop</pre> <p>or by the <code>kill</code> command.</p> <p>Periodically while running, or if terminated or shutdown, the <code>mipagent</code> daemon stores the following internal state information in <code>/var/inet/mipagent_state</code>:</p> <ul style="list-style-type: none">■ a list of the mobile nodes supported as home agents;■ their current care-of addresses; and■ the remaining registration lifetimes. <p>If the <code>mipagent</code> utility is terminated for maintenance and restarted, <code>mipagent_state</code> is used to recreate as much of the mobility agent’s internal state as possible. This minimizes service disruption for mobile nodes that may be visiting other networks. If <code>mipagent_state</code> exists, it is read immediately after <code>mipagent.conf</code> when <code>mipagent</code> is restarted. The format of <code>mipagent_state</code> is undocumented since it is likely to change and programs other than <code>mipagent</code> should not use it for any purpose. A separate utility program <code>mipagentstat</code> is provided for monitoring <code>mipagent</code>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>The daemon started successfully.</td></tr><tr><td>1</td><td>The daemon failed to start.</td></tr></table>	0	The daemon started successfully.	1	The daemon failed to start.
0	The daemon started successfully.				
1	The daemon failed to start.				

FILES /etc/inet/mipagent.conf
Configuration file for Mobile IP mobility agent.

/var/inet/mipagent_state
File where private state information from mipagent is stored.

/etc/init.d/mipagent [start|stop]
mipagent start-up script.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmipu

SEE ALSO mipagentstat(1M), mipagentconfig(1M), syslog(3C), mipagent.conf(4), attributes(5)

Montenegro, G., editor. *RFC 2344, Reverse Tunneling for Mobile IP*. Network Working Group. May 1998.

Perkins, C. *RFC 2002, IP Mobility Support*. Network Working Group. October 1996.

DIAGNOSTICS The mipagent utility exits with an error if the configuration file, mipagent.conf, cannot be read successfully. Upon receiving a SIGTERM or SIGINT signal, mipagent cleans its internal state, including any changes to the routing and ARP tables, and exits.

NOTES The foreign agent adds host-specific local routes to its routing table for visiting mobile nodes after they are successfully registered. If a visiting mobile node departs without sending a de-registration message through the foreign agent, these routing entries persist until the mobile node's previous registration expires. Any packets that arrive at the foreign agent for the departed mobile node during this time, for example because the foreign agent is also a router for the foreign network, will be lost. System administrators can configure foreign agents to accept only short registration lifetimes. This will automatically restrict the maximum duration for which a departed mobile node will be temporarily unreachable.

mipagentconfig(1M)

NAME	mipagentconfig – configure Mobility IP Agent
SYNOPSIS	<code>/sbin/mipagentconfig [-f <i>configfile</i>] <i>command dest</i> [<i>parameters...</i>]</code>
DESCRIPTION	The <code>mipagentconfig</code> utility is used to configure the Mobility IP Agent. It allows the user to change settings and to add and delete mobility clients, Pools, and SPIs in the mobility agent configuration file.
OPTIONS	The following options are supported: <code>-f <i>configfile</i></code> Use the specified configuration file instead of the system default, <code>/etc/inet/mipagent.conf</code> .
OPERANDS	The <i>command</i> operand, as well as the parameters for each command are described below. See <code>mipagent.conf(4)</code> for the default values of the configuration operands described here. <code>add</code> Depending on the destination <i>dest</i> , this command will add advertisement parameters, security parameters, SPIs, or addresses to the configuration file. <code>add Address <i>ipAddress attr_value</i></code> Add the specified <i>ipAddress</i> with the specified SPI. To add an NAI address, you must specify the <code>Pool</code> . <code>add adv <i>device</i></code> Enable home and foreign agent functionality on the specified interface. <code>add adv <i>device AdvLifetime seconds</i></code> Add <code>AdvLifetime</code> to the specified device. <code>add adv <i>device RegLifetime seconds</i></code> Add <code>RegLifetime</code> to the specified device. <code>add adv <i>device AdvFrequency seconds</i></code> Add <code>AdvFrequency</code> to the specified device. <code>add adv <i>device HomeAgent</i> <yes no></code> Add the <code>HomeAgent</code> flag to the specified device. <code>add adv <i>device ForeignAgent</i> <yes no></code> Add the <code>ForeignAgent</code> flag to the specified device. <code>add adv <i>device PrefixLengthExt</i> <yes no></code> Add the <code>PrefixLengthExt</code> flag to the specified device. <code>add adv <i>device NAExt</i> <yes no></code> Add the <code>NAExt</code> flag to the specified device. <code>add adv <i>device Challenge</i> <yes no></code> Add the <code>Challenge</code> flag to the specified device.

```
add adv device ReverseTunnel <no|neither> fa ha
<yes|both>
```

Add the level of ReverseTunnel support indicated to the specified device. Possible values include:

no	Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Does not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.
neither	Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Do not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.
fa	When the foreign agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up to its home agent. If so, perform the necessary encapsulation of datagrams to the mobile node's home agent as described in <i>RFC 2344</i> . This means that a mobile node must see the agent advertising reverse tunnel support, so the reverse tunnel bit is advertised in the agent advertisement on this device.
ha	When the home agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up from its care-of address. If so, perform the necessary decapsulation as described in <i>RFC 2344</i> . This does not mean the home agent is advertising support of reverse tunneling on this device. Mobile nodes are only interested in the advertisement flags if they are going to use foreign agent services. Moreover, reverse tunnels by definition originate at the care-of address, and HA support is therefore only of interest to the owner of the care-of address.
yes	Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting a reverse tunnel be set up. If so, apply <i>RFC</i>

mipagentconfig(1M)

	<p>2344 as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent will be advertising reverse tunnel support on this device.</p>
both	<p>Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting a reverse tunnel be set up. If so, apply RFC 2344 as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent will be advertising reverse tunnel support on this device.</p>
<pre>add adv <i>device</i> ReverseTunnelRequired <no neither> fa ha <yes both></pre>	
<p>Add the requirement that the <code>ReverseTunnel</code> flag be set in any registration request received on the indicated device. Possible values include:</p>	
no	<p>Reverse tunneling is not required by the <code>mipagent</code> on this device.</p>
neither	<p>Reverse tunneling is not required by the <code>mipagent</code> on this device.</p>
fa	<p>The <code>ReverseTunnel</code> flag is required to be set in registration requests received by the foreign agent on this device.</p>
ha	<p>The <code>ReverseTunnel</code> flag is required to be set in registration requests received by the home agent on this device.</p>
yes	<p>The <code>ReverseTunnel</code> flag is required to be set in all registration requests received by either home and or foreign agents on this device.</p>
both	<p>The <code>ReverseTunnel</code> flag is required to be set in all registration requests received by either home and or foreign agents on this device.</p>

	<p><code>add Pool <i>number startAddr length</i></code> Add the specified Pool with the specified start addresses and length.</p> <p><code>add SPI <i>number replay Key</i></code> Add the specified SPI with the given replay type and key. The replay type can have a value of none or timestamps.</p> <p><code>add HA-FAAuth <yes no></code> Add the HA-FAAuth flag.</p> <p><code>add MN-FAAuth <yes no></code> Add the MN-FAAuth flag.</p> <p><code>add MaxClockSkew <i>seconds</i></code> Add the MaxClockSkew.</p> <p><code>add KeyDistribution <i>type</i></code> Add the KeyDistribution type. The only value for KeyDistribution that is supported at this time is file.</p>
change	Depending on the destination <i>dest</i> , this command will change advertisement parameters, security parameters, SPIs, or addresses in the configuration file. Any of the above destinations are valid.
delete	Depending on the destination <i>dest</i> , this command will delete advertisement parameters, security parameters, SPIs, or addresses from the configuration file. Any destination discussed above is valid.
get	Display all of the parameters associated with <i>dest</i> . Any destination discussed above is valid.

EXAMPLES

EXAMPLE 1 Add an SPI, a Pool, and a Mobile Node and Require Reverse Tunneling on a Device to the *configfile*

Use the following example to add an SPI, a Pool, a mobile node, and require reverse tunneling for the foreign agent in the *configfile*. First, the SPI of 250 is added. Then, a Pool of 200 addresses starting at 192.168.168.1 is added.

joe@mobile.com is added with an SPI of 250 and using Pool 1. Finally, reverse tunneling is required for the foreign agent on device 1e0.

```
example# mipagentconfig add SPI 250 ReplayMethod none
example# mipagentconfig add SPI 250 Key 00ff00ff00ff
example# mipagentconfig add Pool 1 192.168.168.1 200
example# mipagentconfig add Address joe@mobile.com 250 1
example# mipagentconfig add 1e0 reversetunnel fa
example# mipagentconfig add 1e0 reversetunnelrequired fa
```

EXAMPLE 2 Modify an SPI

To modify the SPI associated with joe, first, use the command `get` to verify the existing settings, then change the SPI from 250 to 257.

mipagentconfig(1M)

EXAMPLE 2 Modify an SPI *(Continued)*

```
example# mipagentconfig get Address joe@mobile.com
Address: joe@mobile.com
SPI: 250
Pool: 1
example# mipagentconfig change Address joe@mobile.com 257 1
```

EXAMPLE 3 Delete a Pool

Use the following example to delete Pool 3:

```
example# mipagentconfig delete Pool 3
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

FILES

- /etc/inet/mipagent.conf

NAME	mipagentstat – show Mobile IP Mobility Agent status															
SYNOPSIS	mipagentstat [-fh]															
DESCRIPTION	Use the <code>mipagentstat</code> utility to display the content of various Mobile-IP related data structures.															
Visitor Table (First Form)	<p>The visitor table display lists information for all mobile nodes registered with the foreign agent, one mobile node per line. This list consists of the mobile node's home address or Network Access Identifier (NAI), home agent address, total registration lifetime and the number of seconds remaining before the registration expires.</p> <p>The following command line shows the output from a foreign agent with two mobile nodes registered:</p> <pre>example# mipagentstat -f</pre> <table border="0"> <thead> <tr> <th>Mobile Node</th> <th>Foreign Agent</th> <th>Time Granted (in secs)</th> <th>Time Remaining (in secs)</th> <th>Flags</th> </tr> </thead> <tbody> <tr> <td>foobar@xyz.com</td> <td>fal@tuv.com</td> <td>600</td> <td>125</td> <td></td> </tr> <tr> <td>10.1.5.23</td> <td>123.2.5.12</td> <td>1000</td> <td>10</td> <td>R</td> </tr> </tbody> </table> <p>An "R" in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node <code>foobar@xyz.com</code>. A reverse tunnel is configured from mobile node <code>10.1.5.23</code>.</p>	Mobile Node	Foreign Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags	foobar@xyz.com	fal@tuv.com	600	125		10.1.5.23	123.2.5.12	1000	10	R
Mobile Node	Foreign Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags												
foobar@xyz.com	fal@tuv.com	600	125													
10.1.5.23	123.2.5.12	1000	10	R												
Binding Table (Second Form)	<p>The binding table display lists information for all mobile nodes registered with the home agent, one mobile node per line. This list consists of the mobile node's home address or NAI, foreign agent address, total registration lifetime and the number of seconds remaining before the registration expires.</p> <p>Use the following command line to show the output from a home agent with two active mobile nodes:</p> <pre>example# mipagentstat -h</pre> <pre>M</pre> <table border="0"> <thead> <tr> <th>obile Node</th> <th>Home Agent</th> <th>Time Granted (in secs)</th> <th>Time Remaining (in secs)</th> <th>Flags</th> </tr> </thead> <tbody> <tr> <td>foobar@xyz.com</td> <td>hal@xyz.com</td> <td>600</td> <td>125</td> <td></td> </tr> <tr> <td>10.1.5.23</td> <td>10.1.5.1</td> <td>1000</td> <td>10</td> <td>R</td> </tr> </tbody> </table> <p>An "R" in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node <code>foobar@xyz.com</code>. A reverse tunnel is configured for mobile node <code>10.1.5.23</code>.</p>	obile Node	Home Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags	foobar@xyz.com	hal@xyz.com	600	125		10.1.5.23	10.1.5.1	1000	10	R
obile Node	Home Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags												
foobar@xyz.com	hal@xyz.com	600	125													
10.1.5.23	10.1.5.1	1000	10	R												
OPTIONS	<p>-h Display the list of active mobile nodes in the home agent's binding table.</p> <p>-f Display the list of active mobile nodes in the foreign agent's visitor's list.</p>															
EXIT STATUS	<p>The following exit values are returned:</p> <table border="0"> <tr> <td>0</td> <td>Successful completion.</td> </tr> <tr> <td>non-zero</td> <td>An error occurred.</td> </tr> </table>	0	Successful completion.	non-zero	An error occurred.

NAME	mkfifo – make FIFO special file				
SYNOPSIS	<code>/usr/bin/mkfifo [-m <i>mode</i>] <i>path</i>...</code>				
DESCRIPTION	<p>The <code>mkfifo</code> command creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.</p> <p>If errors are encountered in creating one of the special files, <code>mkfifo</code> writes a diagnostic message to the standard error and continues with the remaining arguments, if any.</p> <p>The <code>mkfifo</code> command calls the library routine <code>mkfifo(3C)</code>, with the <i>path</i> argument is passed as the <i>path</i> argument from the command line, and <i>mode</i> is set to the equivalent of <code>a=rw</code>, modified by the current value of the file mode creation mask <code>umask(1)</code>.</p>				
OPTIONS	<p>The following option is supported:</p> <p><code>-m <i>mode</i></code> Set the file permission bits of the newly-created FIFO to the specified <i>mode</i> value. The <i>mode</i> option-argument will be the same as the <i>mode</i> operand defined for the <code>chmod(1)</code> command. In <i><symbolicmode></i> strings, the <i>op</i> characters <code>+</code> and <code>-</code> will be interpreted relative to an assumed initial mode of <code>a=rw</code>.</p>				
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of the FIFO special file to be created.</p>				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>mkfifo</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mkfifo</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 All the specified FIFO special files were created successfully.</p> <p>>0 An error occurred.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu

mkfile(1M)

- NAME** mkfile – create a file
- SYNOPSIS** **mkfile** [-nv] *size* [k | b | m]*filename...*
- DESCRIPTION** *mkfile* creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes *mkfile* (), the sticky bit is set and the file is padded with zeros by default. When non-root users execute *mkfile* (), they must manually set the sticky bit using *chmod*(1). The default *size* is in bytes, but it can be flagged as kilobytes, blocks, or megabytes, with the *k*, *b*, or *m* suffixes, respectively.
- OPTIONS**
- n Create an empty *filename*. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.
 - v Verbose. Report the names and sizes of created files.
- USAGE** See *largefile*(5) for the description of the behavior of *mkfile* when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).
- ATTRIBUTES** See *attributes*(5) for descriptions of the following attributes:

NAME	mkfs – construct a file system						
SYNOPSIS	mkfs [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>raw_device_file</i> [<i>operands</i>]						
DESCRIPTION	<p>The mkfs utility constructs a file system on the <i>raw_device_file</i> by calling the specific mkfs module indicated by -F <i>FSType</i>.</p> <p>Note: ufs file systems are normally created with the newfs(1M) command.</p> <p><i>generic_options</i> are independent of file system type. <i>FSType-specific_options</i> is a comma-separated list of <i>keyword=value</i> pairs (with no intervening spaces), which are <i>FSType</i>-specific. <i>raw_device_file</i> specifies the disk partition on which to write the file system. It is required and must be the first argument following the <i>specific_options</i> (if any). <i>operands</i> are <i>FSType</i>-specific. See the <i>FSType</i>-specific manual page of mkfs (for example, mkfs_ufs(1M)) for a detailed description.</p>						
OPTIONS	<p>The following are the generic options for mkfs:</p> <ul style="list-style-type: none"> -F Specify the <i>FSType</i> to be constructed. If -F is not specified, the <i>FSType</i> is determined from <code>/etc/vfstab</code> by matching the <i>raw_device_file</i> with a <code>vfstab</code> entry, or by consulting the <code>/etc/default/fs</code> file. -V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from <code>/etc/vfstab</code> or <code>/etc/default/fs</code>. This option may be used to verify and validate the command line. -m Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system. -o Specify <i>FSType</i>-specific options. See the manual page for the mkfs module specific to the file system type. 						
USAGE	See largefile(5) for the description of the behavior of mkfs when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).						
FILES	<table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top;"><code>/etc/default/fs</code></td> <td>Default file system type. Default values can be set for the following flags in <code>/etc/default/fs</code>. For example: <code>LOCAL=ufs</code></td> </tr> <tr> <td style="vertical-align: top;"><code>LOCAL</code></td> <td>The default partition for a command if no <i>FSType</i> is specified.</td> </tr> <tr> <td style="vertical-align: top;"><code>/etc/vfstab</code></td> <td>List of default parameters for each file system</td> </tr> </table>	<code>/etc/default/fs</code>	Default file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example: <code>LOCAL=ufs</code>	<code>LOCAL</code>	The default partition for a command if no <i>FSType</i> is specified.	<code>/etc/vfstab</code>	List of default parameters for each file system
<code>/etc/default/fs</code>	Default file system type. Default values can be set for the following flags in <code>/etc/default/fs</code> . For example: <code>LOCAL=ufs</code>						
<code>LOCAL</code>	The default partition for a command if no <i>FSType</i> is specified.						
<code>/etc/vfstab</code>	List of default parameters for each file system

NOTES This command may not be supported for all *FSTypes*.

NAME	mkfs_pcfs – construct a FAT file system
SYNOPSIS	mkfs -F pcfs [<i>generic_options</i>] [-o <i>FSType_specific_options</i>] <i>raw_device_file</i>
DESCRIPTION	<p>The pcfs-specific module of mkfs constructs a File Allocation Table (FAT) on removable media (diskette, JAZ disk, ZIP disk, PCMCIA card) or a hard disk. FATs are the standard MS-DOS and Windows file system format. Note that you can use fdformat(1) to construct a FAT file system only on a diskette or PCMCIA card.</p> <p>mkfs for pcfs determines an appropriate FAT size for the media, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. mkfs for pcfs can also install the initial file in the file system (see the pcfs-specific -o i option). This first file can optionally be marked as read-only, system, and/or hidden.</p> <p>If you want to construct a FAT with mkfs for pcfs on media that is not formatted, you must first perform a low-level format on the media with fdformat(1) or format(1M). Non-diskette media must also be partitioned with the fdisk(1M) utility. Note that all existing data on the diskette or disk partition, if any, is destroyed when a new FAT is constructed.</p> <p><i>generic_options</i> are supported by the generic mkfs command. See mkfs(1M) for a description of these options.</p> <p><i>raw_device_file</i> indicates the device on which to write unless the -o N option has been specified, or if the -v or -m generic options are passed from the generic mkfs module.</p>
OPTIONS	<p>See mkfs(1M) for the list of supported generic options.</p> <p>The following options are supported:</p> <p>-o <i>FSType_specific_options</i> Specify pcfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.</p> <p>b=label Label the media with volume label. The volume label is restricted to 11 uppercase characters.</p> <p>B=filename Install <i>filename</i> as the boot loader in the file system's boot sector. If you don't specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make the diskette bootable. See NOTES for more information.</p> <p>fat=n The size of a FAT entry. Currently, only 12 and 16 are valid values. The default is 12 for diskettes, 16 for larger media.</p> <p>h Mark the first file installed as a hidden file. The -i option must also be specified.</p> <p>hidden=n Set the number of hidden sectors to <i>n</i>. This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to 0 for diskettes or a computed</p>

mkfs_pcfs(1M)

		valued (based on the fdisk table) for disks. This option may be used only in conjunction with the <code>nofdisk</code> option.
	<code>i=filename</code>	Install <i>filename</i> as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.
	<code>nofdisk</code>	Do not attempt to find an fdisk table on the media, instead rely on the <code>size</code> option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the hidden option (<code>-h</code>).
	<code>nsect=n</code>	The number of sectors per track on the disk. If not specified, the value is determined by using a <code>dkio(7I)</code> ioctl to get the disk geometry, or (for diskette) from the results of an <code>FDIOGCHAR</code> ioctl.
	<code>ntrack=n</code>	The number of tracks per cylinder on the disk. If not specified, the value is determined by using a <code>dkio(7I)</code> ioctl to get the disk geometry, or (for diskette) from the results of an <code>FDIOGCHAR</code> ioctl.
	<code>N</code>	No execution mode. Print normal output, but do not actually write the file system to the media. This is most useful when used in conjunction with the <code>verbose</code> option.
	<code>r</code>	Mark the first file installed as read-only. The <code>-i</code> option must also be specified.
	<code>reserve=n</code>	Set the number of reserved sectors to <i>n</i> . This is the number of sectors in the volume, preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.
	<code>s</code>	Mark the first file installed as a system file. The <code>-i</code> option must also be specified.
	<code>size=n</code>	The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table or (for diskette) by way of computation using the <code>FDIOGCHAR</code> ioctl.
	<code>spc=n</code>	The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.
	<code>v</code>	Verbose output. Describe, in detail, operations being performed.
FILES	<code>raw_device_file</code>	The device on which to build the FAT. The device name for a diskette must be specified as <code>/dev/rdiskette0</code> for the first diskette drive, or <code>/dev/rdiskette1</code> for a second diskette drive. For non-diskette media, a disk device name must be qualified with a suffix to indicate the proper partition. For example, in the name <code>/dev/rdisk/c0t0d0p0:c</code> , the <code>:c</code> suffix indicates that

the first partition on the disk should receive the new FAT.

EXAMPLES The media in these examples must be formatted before running `mkfs` for `pcfs`. See `DESCRIPTION` for more details.

EXAMPLE 1 Creating a FAT File System on a Diskette

The following command creates a FAT file system on a diskette:

```
mkfs -F pcfs /dev/rdiskette
```

EXAMPLE 2 Creating a FAT File System on a Disk

The following command creates a FAT file system on the second fdisk partition of a disk attached to an IA based system:

```
mkfs -F pcfs /dev/rdisk/c0d0p0:d
```

EXAMPLE 3 Creating a FAT File System on a ZIP Disk

The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

```
mkfs -F pcfs /dev/rdisk/c0t4d0s2:c
```

EXAMPLE 4 Creating a FAT File System on a JAZ Disk

The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

```
mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdisk/c0t3d0s2:c
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Stable

SEE ALSO `fdformat(1)`, `fdisk(1M)`, `format(1M)`, `mkfs(1M)`, `attributes(5)`, `fd(7D)`, `dkio(7I)`, `fdio(7I)`

NOTES The default MS-DOS boot loader, which is installed by default if `-o B` is not specified, requires specific MS-DOS system files to make the diskette bootable. These MS-DOS files are not installed when you format a diskette with `mkfs` for `pcfs`, which makes a

mkfs_pcfs(1M)

diskette formatted this way not bootable. Trying to boot from it on an IA based system will result in the following message:

```
Non-System disk or disk error  
Replace and strike any key when ready
```

You must format a diskette with the DOS `format` command to install the specific MS-DOS system files required by the default boot loader.

mkfs_udfs(1M)

Device is in use, cannot create file system when the device is in use.

preposterous size

Negative size parameter provided is invalid.

sector size must be between 512, 8192 bytes

Sector size given is not in the valid range.

Volume integrity sequence descriptors too long

File set descriptor too long.

Not enough space to create volume integrity sequence or file set descriptor.

mkfs: argument out of range

One of the arguments is out of range.

mkfs: bad numeric arg

One of the arguments is potentially a bad numeric.

NAME	mkfs_ufs – construct a ufs file system
SYNOPSIS	mkfs -F ufs [<i>generic_options</i>] [-o <i>FSType_specific_options</i>] <i>raw_device_file</i> [<i>size</i>]
DESCRIPTION	<p>The ufs-specific module of mkfs builds a ufs file system with a root directory and a <code>lost+found</code> directory (see fsck(1M))</p> <p>The ufs-specific mkfs is rarely run directly; use the newfs(1M) command instead.</p> <p><i>raw_device_file</i> indicates the disk partition to write on unless the <code>-o N</code> option has been specified, or either the <code>-V</code> or <code>-m</code> generic options are passed from the generic mkfs module. <i>size</i> specifies the number of sectors in the file system. This argument must follow the <i>raw_device_file</i> argument and is required (even with <code>-o N</code>), unless the <code>-V</code> or <code>-m</code> generic options are specified.</p> <p><i>generic_options</i> are supported by the generic mkfs command. See mkfs(1M) for a description of these options.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -o Use one or more of the following values separated by commas (with no intervening spaces) to specify ufs-specific options: <ul style="list-style-type: none"> N Print out the file system parameters without actually creating the file system. nsect=<i>n</i> The number of sectors per track on the disk. The default is 32. ntrack=<i>n</i> The number of tracks per cylinder on the disk. The default is 16. bsize=<i>n</i> Logical block size, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size. fragsize=<i>n</i> The smallest amount of disk space in bytes to allocate to a file. The smallest amount of disk space in bytes to allocate to a file. If the logical block size is 4096, legal values are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024. cgsize=<i>n</i> The number of cylinders per cylinder group (ranging from 16 to 256). The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte, and then multiplying the result by 32. The default value will always be between 16 and 256. The per-cylinder-group meta data must fit in a space no larger than that available in one logical file system block. If too large a <i>cgsize</i> is requested, it is decreased by the minimum amount necessary.

mkfs_ufs(1M)

<code>free=<i>n</i></code>	The minimum percentage of free space to maintain in the file system. This space is off-limits to normal users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command. The default is 10%.
<code>rps=<i>n</i></code>	The rotational speed of the disk, in revolutions per second. The default is 60.
<code>nbpi=<i>n</i></code>	The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the fixed number of inodes to create. It should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used; to create more inodes, a smaller number should be given. The default is 2048.
<code>opt=<i>a</i></code>	Space or time optimization preference; <i>s</i> specifies optimization for space, <i>t</i> specifies optimization for time. The default is <i>t</i> . This parameter may be subsequently changed with the <code>tunefs(1M)</code> command.
<code>apc=<i>n</i></code>	The number of alternates per cylinder to reserve for bad block replacement (SCSI devices only). The default is 0.
<code>gap=<i>n</i></code>	Rotational delay. The expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. The value is used to decide how much rotational spacing to place between successive blocks in a file. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command. The default is disk-type dependent.
<code>nrpos=<i>n</i></code>	The number of different rotational positions in which to divide a cylinder group. The default is 8.
<code>maxcontig=<i>n</i></code>	The maximum number of blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay. For a 4K file system, the default is 14; for an 8K file system it is 7. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command. This parameter also controls clustering. Regardless of the value of <i>gap</i> , clustering is enabled only when <code>maxcontig</code> is greater than 1. Clustering allows higher I/O rates for sequential I/O and is described in

tunefs(1M).

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the `-o` option is omitted and the list follows the size operand. This is the way `newfs` passes the parameters to `mkfs`.

OPERANDS The following operands are supported:

raw_device_file The disk partition on which to write.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fsck(1M)`, `mkfs(1M)`, `newfs(1M)`, `tunefs(1M)`, `dir_ufs(4)`, `fs_ufs(4)`, `attributes(5)`

DIAGNOSTICS The following error message occurs typically on very high density disks. On such disks, the file system structure cannot encode the proper disk layout information, resulting in suboptimal performance.

```
Warning: insufficient space in super block for
rotational layout tables with nsect sblock.fs_nsect
and ntrak sblock.fs_ntrak. (File system performance may be impaired.)
```

The following error message occurs if a user request for inodes or bytes (with the `nbpi` keyword) and the disk geometry results in a situation in which the last truncated cylinder group cannot contain the correct number of data blocks; some disk space is wasted.

```
Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder
```

The following error message occurs if the user parameters and disk geometry conflict; some disk space is lost. A possible cause is the specified size being smaller than the partition size.

```
Warning: num sector(s) in last cylinder group unallocated
```

mknod(1M)

NAME	mknod – make a special file				
SYNOPSIS	mknod <i>name</i> <i>b</i> <i>major</i> <i>minor</i> mknod <i>name</i> <i>c</i> <i>major</i> <i>minor</i> mknod <i>name</i> <i>p</i>				
DESCRIPTION	mknod makes a directory entry for a special file.				
OPTIONS	The following options are supported: <i>b</i> Create a block-type special file. <i>c</i> Create a character-type special file. <i>p</i> Create a FIFO (named pipe).				
OPERANDS	The following operands are supported: <i>major</i> The <i>major</i> device number. <i>minor</i> The <i>minor</i> device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command. <i>name</i> A special file to be created.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>mknod</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>ftp(1)</code> , <code>in.ftpd(1M)</code> , <code>mknod(2)</code> , <code>symlink(2)</code> , <code>attributes(5)</code> , <code>largefile(5)</code>				
NOTES	If <code>mknod(2)</code> is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine. With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the <code>/devices</code> subtree) rather than using <code>mknod</code> .				

NAME	modinfo – display information about loaded kernel modules				
SYNOPSIS	<code>/usr/sbin/modinfo [-c] [-w] [-i <i>module-id</i>]</code>				
DESCRIPTION	<p>The <code>modinfo</code> utility displays information about the loaded modules. The format of the information is as follows:</p> <pre><i>Id Loadaddr Size Info Rev Module Name</i> Where <i>Id</i> is the module ID, <i>Loadaddr</i> is the starting text address in hexadecimal, <i>Size</i> is the size of text, data, and bss in hexadecimal bytes, <i>Info</i> is module specific information, <i>Rev</i> is the revision of the loadable modules system, and <i>Module Name</i> is the filename and description of the module.</pre> <p>The module specific information is the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table:</p> <pre>fmodsw for STREAMS modules vfssw for filesystems class for scheduling classes execsw for exec modules</pre>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -c Displays the number of instances of the module loaded and the module's current state. -i <i>module-id</i> Displays information about this module only. -w Does not truncate module information at 80 characters. 				
EXAMPLES	<p>EXAMPLE 1 Using the <code>modinfo</code> command.</p> <p>The following example displays the status of module 3:</p> <pre>example% modinfo -i 3 <i>Id Loadaddr Size Info Rev Module Name</i> 3 f5a7a000 3bc0 1 1 spedfs (filesystem for specfs)</pre>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>modload(1M)</code> , <code>modunload(1M)</code> , <code>attributes(5)</code>				

modload(1M)

NAME	modload – load a kernel module				
SYNOPSIS	modload [-p] [-e <i>exec_file</i>] <i>filename</i>				
DESCRIPTION	<p>modload loads the loadable module <i>filename</i> into the running system. <i>filename</i> is an object file produced by <code>ld -r</code>. If <i>filename</i> is an absolute pathname then the file specified by that absolute path is loaded. If <i>filename</i> does not begin with a '/' then the path to load <i>filename</i> is relative to the current directory unless the <code>-p</code> option is specified. The kernel's <code>modpath</code> variable can be set using the <code>/etc/system</code> file. The default value of the kernel's <code>modpath</code> variable is set to the path where the operating system was loaded. Typically this is <code>/kernel /usr/kernel</code>. Hence if you type:</p> <pre>example# modload drv/foo</pre> <p>The kernel will look for <code>./drv/foo</code>.</p> <p>If you type:</p> <pre>example# modload -p drv/foo</pre> <p>The kernel will look for <code>/kernel/drv/foo</code> and then <code>/usr/kernel/drv/foo</code>.</p>				
OPTIONS	<p><code>-p</code> Use the kernel's internal <code>modpath</code> variable as the search path for the module.</p> <p><code>-e <i>exec_file</i></code> Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See <code>modinfo(1M)</code></p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<p><code>ld(1)</code>, <code>add_drv(1M)</code>, <code>kernel(1M)</code>, <code>modinfo(1M)</code>, <code>modunload(1M)</code>, <code>system(4)</code>, <code>attributes(5)</code>, <code>modldrv(9S)</code>, <code>modlinkage(9S)</code>, <code>modlstrmod(9S)</code>, <code>module_info(9S)</code></p> <p><i>Writing Device Drivers</i></p> <p><i>Solaris Transition Guide</i></p>				
NOTES	Use <code>add_drv(1M)</code> to add device drivers, not <code>modload</code> . See <i>Writing Device Drivers</i> for procedures on adding device drivers.				

NAME	modunload – unload a module				
SYNOPSIS	modunload -i <i>module_id</i> [-e <i>exec_file</i>]				
DESCRIPTION	modunload unloads a loadable module from the running system. The <i>module_id</i> is the ID of the module as shown by modinfo(1M). If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by modload(1M) are not affected.				
OPTIONS	<p>-i <i>module_id</i> Specify the module to be unloaded.</p> <p>-e <i>exec_file</i> Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second and third arguments are the block major and character major numbers respectively. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the <i>execsw</i> table. For loadable filesystems, the second argument is the index into the <i>vfssw</i> table. For loadable streams modules, the second argument is the index into the <i>fmodsw</i> table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

mofcomp(1M)

NAME	mofcomp – compile MOF files into CIM classes										
SYNOPSIS	<pre>/usr/sadm/bin/mofcomp [-help] [-v] [-sc] [-si] [-sq] [-version] [-c <i>cimom_hostname</i>] [-o <i>dirname</i>] [-p <i>password</i>] [-u <i>username</i>] [-x] <i>file</i></pre>										
DESCRIPTION	<p>The <code>mofcomp</code> utility is executed during installation to compile MOF files that describe the CIM and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.</p> <p>The <code>mofcomp</code> utility must be run as root or as a user with write access to the namespace in which you are compiling.</p> <p>MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.</p> <p>Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the <code>mofcomp</code> utility to compile MOF files at any time after installation.</p>										
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-c <i>cimom_hostname</i></code></td><td>Specify a remote system running the CIM Object Manager.</td></tr><tr><td><code>-help</code></td><td>List the arguments to the <code>mofcomp</code> utility.</td></tr><tr><td><code>-o <i>dirname</i></code></td><td>Run compiler in standalone mode, without the CIM Object Manager. Specify <i>dirname</i> as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.</td></tr><tr><td><code>-p <i>password</i></code></td><td>Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both <code>-p</code> and <code>-u</code>, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify <code>-u</code> but not <code>-p</code>, so that the compiler will prompt for the password.</td></tr><tr><td><code>-sc</code></td><td>Run the compiler with the set class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option,</td></tr></table>	<code>-c <i>cimom_hostname</i></code>	Specify a remote system running the CIM Object Manager.	<code>-help</code>	List the arguments to the <code>mofcomp</code> utility.	<code>-o <i>dirname</i></code>	Run compiler in standalone mode, without the CIM Object Manager. Specify <i>dirname</i> as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.	<code>-p <i>password</i></code>	Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both <code>-p</code> and <code>-u</code> , you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify <code>-u</code> but not <code>-p</code> , so that the compiler will prompt for the password.	<code>-sc</code>	Run the compiler with the set class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option,
<code>-c <i>cimom_hostname</i></code>	Specify a remote system running the CIM Object Manager.										
<code>-help</code>	List the arguments to the <code>mofcomp</code> utility.										
<code>-o <i>dirname</i></code>	Run compiler in standalone mode, without the CIM Object Manager. Specify <i>dirname</i> as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.										
<code>-p <i>password</i></code>	Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both <code>-p</code> and <code>-u</code> , you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify <code>-u</code> but not <code>-p</code> , so that the compiler will prompt for the password.										
<code>-sc</code>	Run the compiler with the set class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option,										

the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.

-si	Run the compiler with the set instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.
-sq	Run the compiler with the set qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.
-u <i>username</i>	Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u , you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p , so that the compiler will prompt for the password.
-v	Run the compiler in verbose mode, which displays compiler messages.
-version	Display the version of the MOF compiler.
-x	Generate XML documents for the CIM classes defined in the input MOF file.

OPERANDS The following operands are supported:

file The pathname of the file to be compiled.

EXIT STATUS The `mofcomp` utility exits with 0 upon success and a positive integer upon failure.

FILES The MOF files that describe the CIM Version 1 and Version 2 Schema and the Solaris Schema are:

mofcomp(1M)

NAME	monitor – SPARC system PROM monitor
SYNOPSIS	<p>L1-A</p> <p>BREAK</p> <p>initial system power-on</p> <p>exit from a client program, e.g., the Operating System</p>
DESCRIPTION	<p>The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as “the monitor”. Among other things, the monitor performs system initialization at power-on and provides a user interface.</p>
Monitor Prompt	<p>The monitor of earlier workstations was known as the SunMON monitor and displayed the > for its prompt. See the SunMON MONITOR USAGE section for further details.</p> <p>Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the > prompt under certain circumstances.</p> <p>If the 'auto-boot?' NVRAM parameter is set to 'false' when the workstation is powered on then the system will not attempt to boot and the monitor will issue its prompt. If 'auto-boot' is set to 'true' then the system will initiate the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Note that either a lower case 'a' or an upper case 'A' will work for the keyboard abort sequence. If a console has been attached via one of the system's serial ports then the abort sequence can be accomplished by sending a BREAK – see the tip(1) manpage.</p> <p>When the NVRAM 'security-mode' parameter has been turned on, or when the value of the 'sunmon-compat?' parameter is true, then the OpenBoot monitor will display the message:</p> <p>Type b (boot), c (continue), or n (new command mode)</p> <p>and the > prompt will appear.</p>
OPENBOOT PROM USAGE	<p>Some of the more useful commands that can be issued from OpenBoot's ok prompt are described here. Refer to the <i>OpenBoot 3.x Command Reference Manual</i> book for a complete list of commands.</p>
Help	<p>Help for various functional areas of the OpenBoot monitor can be obtained by typing help. The help listing will provide a number of other key words which can then be used in the help command to provide further details.</p>
NVRAM Parameters	<p>Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM</p>

monitor(1M)

parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

See the `eeeprom(1M)` manpage for a description of the parameters. This manpage also describes a way of setting the parameters from the OS level.

The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

- | | |
|------------------------------------|---|
| <code>printenv</code> | Used to list the NVRAM parameters, along with their default values and current values. |
| <code>setenv <i>pn pv</i></code> | Used to set or modify a parameter. The <i>pn</i> represents the parameter name, and <i>pv</i> represents the parameter value. |
| <code>set-default <i>pn</i></code> | Used to set an individual parameter back to its default value. |
| <code>set-defaults</code> | Used to reset all parameters to their default values. (Note that 'set-defaults' only affects parameters that have assigned default values.) |

Hardware Checks and Diagnostics

The following commands are available for testing or checking the system's hardware. If the 'diag-switch?' NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic will be run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.

- | | |
|----------------------------|--|
| <code>test-all</code> | Run the diagnostic tests on each device which has provided a self-test. |
| <code>test floppy</code> | Run diagnostics on the system's floppy device. |
| <code>test /memory</code> | Run the main memory tests. If the NVRAM parameter 'diag-switch?' is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the 'selftest-#megs' NVRAM parameter will be tested. |
| <code>test net</code> | Test the network connection for the on-board network controller. |
| <code>watch-net</code> | Monitor the network attached to the on-board net controller. |
| <code>watch-net-all</code> | Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots. |
| <code>watch-clock</code> | Test the system's clock function. |

System Information

The following commands are available for displaying information about the system. Not all commands are available on all workstations.

- | | |
|-------------------------|---|
| <code>banner</code> | Display the power-on banner. |
| <code>.enet-addr</code> | Display the system's Ethernet address. |
| <code>.idprom</code> | Display the formatted contents of the IDPROM. |

<code>module-info</code>	Display information about the system's processor(s).
<code>probe-scsi</code>	Identify the devices attached to the on-board SCSI controller.
<code>probe-scsi-all</code>	Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
<code>show-disks</code>	Display a list of the device paths for installed SCSI disk controllers.
<code>show-displays</code>	Display a list of the device paths for installed display devices.
<code>show-nets</code>	Display a list of the device paths for installed Ethernet controllers.
<code>show-sbus</code>	Display list of installed SBus devices.
<code>show-tapes</code>	Display a list of the device paths for installed SCSI tape controllers.
<code>show-ttys</code>	Display a list of the device paths for tty devices.
<code>.traps</code>	Display a list of the SPARC trap types.
<code>.version</code>	Display the version and date of the OpenBoot PROM.

Emergency Commands

These commands must be typed from the keyboard, they will not work from a console which is attached via the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

Stop (L1)	Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
Stop-A (L1-A)	Abort the current operation and return to the monitor's default prompt.
Stop-D (L1-D)	Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, will be run, and the messages will be displayed via the system's serial port A.
Stop-F (L1-F)	Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.

monitor(1M)

	<p>Stop-N (L1-N) Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.</p>
Line Editor Commands	<p>The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.</p> <p>CTRL-A Place the cursor at the start of line.</p> <p>CTRL-B Move the cursor backward one character.</p> <p>ESC-B Move the cursor backward one word.</p> <p>CTRL-D Erase the character that the cursor is currently highlighting.</p> <p>ESC-D Erase the portion of word from the cursor's present position to the end of the word.</p> <p>CTRL-E Place the cursor at the end of line.</p> <p>CTRL-F Move the cursor forward one character.</p> <p>ESC-F Move the cursor forward one word.</p> <p>CTRL-H Erase the character preceding the cursor (also use Delete or Back Space)</p> <p>ESC-H Erase the portion of the word which precedes the cursor (use also CTRL-W)</p> <p>CTRL-K Erase from the cursor's present position to the end of the line.</p> <p>CTRL-L Show the command history list.</p> <p>CTRL-N Recall the next command from the command history list</p> <p>CTRL-P Recall a previous command from the command history list.</p> <p>CTRL-Q Quote the next character (used to type a control character).</p> <p>CTRL-R Retype the current line.</p> <p>CTRL-U Erase from the cursor's present position to the beginning of the line.</p> <p>CTRL-Y Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.</p>
nvrामrc	<p>The nvrामrc is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the nvrामrc will executed each time the system is reset, provided that the 'use-nvrामrc?' NVRAM parameter has been set to 'true'. Refer to the <i>OpenBoot 3.x Command Reference Manual</i> book for information on how to edit and use the nvrामrc.</p>
Restricted Monitor	<p>The command 'old-mode' is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the 'go' command (to resume a program which was interrupted with the Stop-A command), the 'n' command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands</p>

SunMON PROM
USAGE

will approximate the older SunMON monitor's boot command syntax. If a 'security-mode' has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the 'sunmon-compat?' NVRAM parameter is set to true. (Note that not all workstations will have the 'sunmon-compat?' parameter.)

The following commands are available systems with older SunMON-based PROM:

+|-

Increment or decrement the current address and display the contents of the new location.

^C *source destination n*

(caret-C) Copy, byte-by-byte, a block of length *n* from the *source* address to the *destination* address.

^I *program*

(caret-I) Display the compilation date and location of *program*.

^T *virtual_address*

(caret-T) Display the physical address to which *virtual_address* is mapped.

b [!] [*device* [(*c, u, p*)]] [*pathname*] [*arguments_list*]

b[?]

Reset appropriate parts of the system and bootstrap a program. A '!' (preceding the *device* argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). 'b' with no arguments will cause a default boot, either from a disk, or from an Ethernet controller. 'b?' displays all boot devices and their *devices*.

<i>device</i>	one of
	le Lance Ethernet
	ie Intel Ethernet
	sd SCSI disk, CDROM
	st SCSI 1/4" or 1/2" tape
	fd Diskette
	id IPI disk
	mt Tape Master 9-track 1/2" tape
	xd Xylogics 7053 disk
	xt Xylogics 1/2" tape
	xy Xylogics 440/450 disk
<i>c</i>	A controller number (0 if only one controller),
<i>u</i>	A unit number (0 if only one driver), and

monitor(1M)

<i>p</i>	A partition.
<i>pathname</i>	A pathname for a program such as <code>/stand/diag</code> .
<i>arguments_list</i>	A list of up to seven arguments to pass to the program being booted.
c [<i>virtual_address</i>]	Resume execution of a program. When given, <i>virtual_address</i> is the address at which execution will resume. The default is the current PC. Registers are restored to the values shown by the <code>d</code> , and <code>r</code> commands.
d [<i>window_number</i>]	Display (dump) the state of the processor. The processor state is observable only after: <ul style="list-style-type: none">■ An unexpected trap was encountered.■ A user program dropped into the monitor (by calling <i>abortent</i>).■ The user manually entered the monitor by typing <code>L1-A</code> or <code>BREAK</code>. The display consists of the following: <ul style="list-style-type: none">■ The special registers: PSR, PC, nPC, TBR, WIM, and Y■ Eight global registers■ 24 window registers (8 <i>in</i>, 8 <i>local</i>, and 8 <i>out</i>), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.
<i>window_number</i>	Display the indicated <i>window_number</i> , which can be any value between 0 and 6, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.
e [<i>virtual_address</i>] [<i>action</i>] . . .	Open the 16-bit word at <i>virtual_address</i> (default zero). The address is interpreted in the address space defined by the <code>s</code> command. See the <code>a</code> command for a description of <i>action</i> .
f <i>virtual_address1</i> <i>virtual_address2</i> <i>pattern</i> [<i>size</i>]	Fill the bytes, words, or long words from <i>virtual_address1</i> (lower) to <i>virtual_address2</i> (higher) with the constant, <i>pattern</i> . The <i>size</i> argument can take one of the following values: <ul style="list-style-type: none">b byte format (the default)w word formatl long word format

For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

f 1000 2000 ABCD W

g [*vector*] [*argument*]

g [*virtual_address*] [*argument*]

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's g command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x hexadecimal

%d decimal

g0

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

g4

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

h

Display the help menu for monitor commands and their descriptions. To return to the monitor's basic command level, press ESCAPE or q before pressing RETURN.

i [*cache_data_offset*] [*action*] . . .

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the a command for a description of *action*.

j [*cache_tag_offset*] [*action*] . . .

Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the a command for a description of *action*.

k [*reset_level*]

Reset the system, where *reset_level* is:

0 Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.

1 Software reset.

2 Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

monitor(1M)

- kb
Display the system banner.
- l [*virtual_address*] [*action*] . . .
Open the long word (32 bit) at memory address *virtual_address* (default zero). The address is interpreted in the address space defined by the *s* command (below). See the *a* command for a description of *action*.
- m [*virtual_address*] [*action*] . . .
Open the segment map entry that maps *virtual_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.
- ne
- ni
Disable, enable, or invalidate the cache, respectively.
- o [*virtual_address*] [*action*] . . .
Open the byte location specified by *virtual_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.
- p [*virtual_address*] [*action*] . . .
Open the page map entry that maps *virtual_address* (default zero) in the address space defined by the *s* command. See the *a* command for a description of *action*.
- q [*eeeprom_offset*] [*action*] . . .
Open the EEPROM *eeeprom_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the *a* command for a description of *action*.
- r [*register_number*]
r [*register_type*]
r [*w window_number*]
Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register_number* can be one of:
- | | |
|-----------|---|
| 0x00–0x0f | window(0,i0)–window(0,i7),
window(0,i0)—window(0,i7) |
| 0x16–0x1f | window(1,i0)–window(1,i7),
window(1,i0)—window(1,i7) |
| 0x20–0x2f | window(2,i0)–window(2,i7),
window(2,i0)—window(2,i7) |
| 0x30–0x3f | window(3,i0)–window(3,i7),
window(3,i0)—window(3,i7) |

0x40–0x4f	window(4,i0)–window(4,i7), window(4,i0)–window(4,i7)
0x50–0x5f	window(5,i0)–window(5,i7), window(5,i0)–window(5,i7)
0x60–0x6f	window(6,i0)–window(6,i7), window(6,i0)–window(6,i7)
0x70–0x77	g0, g1, g2, g3, g4, g5, g6, g7
0x78–0x7d	PSR, PC, nPC, WIM, TBR, Y.
0x7e–0x9e	FSR, f0–f31

Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the *abortent* function, or the user has entered the monitor by manually typing L1–A or BREAK.

If a *register_type* is given, the first register of the indicated type is displayed. *register_type* can be one of:

f	floating-point
g	global
s	special

If *w* and a *window_number* (0–6) are given, the first *in*-register within the indicated window is displayed. If *window_number* is omitted, the window that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

s [*asi*]

Set or display the Address Space Identifier. With no argument, *s* displays the current Address Space Identifier. The *asi* value can be one of:

0x2	control space
0x3	segment table
0x4	Page table
0x8	user instruction
0x9	supervisor instruction
0xa	user data
0xb	supervisor data
0xc	flush segment
0xd	flush page
0xe	flush context

monitor(1M)

0xf cache data

u [echo]

u [port] [options] [baud_rate]

u [u] [virtual_address]

With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the *u* argument (uu. . .), set the I/O device to be the *virtual_address* of a UART device currently mapped.

echo Can be either *e* to enable input to be echoed to the output device, or *ne*, to indicate that input is not echoed.

port Assign the indicated *port* to be the current I/O device. *port* can be one of:

- a* serial port A
- b* serial port B
- k* the workstation keyboard
- s* the workstation screen

baud_rate Any legal baud rate.

options can be any combination of:

- i* input
- o* output
- u* UART
- e* echo input to output
- ne* do not echo input
- r* reset indicated serial port (a and b ports only)

If either *a* or *b* is supplied, and no *options* are given, the serial port is assigned for both input and output. If *k* is supplied with no options, it is assigned for input only. If *s* is supplied with no options, it is assigned for output only.

v *virtual_address1* *virtual_address2* [size]

Display the contents of *virtual_address1* (lower) *virtual_address2* (higher) in the format specified by *size*:

- b* byte format (the default)
- w* word format

1 long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

```
v 1000 2000 W
```

w [*virtual_address*] [*argument*]

Set the execution vector to a predetermined or default routine. Pass *virtual_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's w command, set the variable *romp->v_vector_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x hexadecimal

%d decimal

x

Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

y c *context_number*

y p|s *context_number virtual_address*

Flush the indicated context, context page, or context segment.

c flush context *context_number*

p flush the page beginning at *virtual_address* within context *context_number*

s flush the segment beginning at *virtual_address* within context *context_number*

OpenBoot 3.x Command Reference Manual

NAME	mount, umount – mount or unmount file systems and remote resources
SYNOPSIS	<pre> mount [-p -v] mount [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -a [-F <i>FSType</i>] [-V] [<i>current_options</i>] [-o <i>specific_options</i>] [<i>mount_point...</i>] umount [-f] [-V] [-o <i>specific_options</i>] <i>special</i> <i>mount_point</i> umount -a [-f] [-V] [-o <i>specific_options</i>] [<i>mount_point...</i>] </pre>
DESCRIPTION	<p>mount attaches a file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>umount unmounts a currently mounted file system, which may be specified either as a <i>mount_point</i> or as <i>special</i>, the device on which the file system resides.</p> <p>The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on <i>/etc/mnttab</i>. The mounted file system information is described in <i>mnttab(4)</i>. Mounting a file system adds an entry to the mount table; a umount removes an entry from the table.</p> <p>When invoked with both the <i>special</i> and <i>mount_point</i> arguments and the <i>-F</i> option, mount validates all arguments except for <i>special</i> and invokes the appropriate <i>FSType</i>-specific mount module. If invoked with no arguments, mount lists all the mounted file systems recorded in the mount table, <i>/etc/mnttab</i>. If invoked with a partial argument list (with only one of <i>special</i> or <i>mount_point</i>, or with both <i>special</i> or <i>mount_point</i> specified but not <i>FSType</i>), mount will search <i>/etc/vfstab</i> for an entry that will supply the missing arguments. If no entry is found, and the <i>special</i> argument starts with <i>/</i>, the default local file system type specified in <i>/etc/default/fs</i> will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the <i>/etc/dfs/fstypes</i> file. After filling in missing arguments, mount will invoke the <i>FSType</i>-specific mount module.</p> <p>Only a super-user can mount or unmount file systems using mount and umount. However, any user can use mount to list mounted file systems and resources.</p>
OPTIONS	<p><i>-F FSType</i></p> <p>Used to specify the <i>FSType</i> on which to operate. The <i>FSType</i> must be specified or must be determinable from <i>/etc/vfstab</i>, or by consulting <i>/etc/default/fs</i> or <i>/etc/dfs/fstypes</i>.</p>

mount(1M)

-a [*mount_points*. . .]

Perform mount or umount operations in parallel, when possible.

If mount points are not specified, mount will mount all file systems whose */etc/vfstab* "mount at boot" field is "yes". If mount points are specified, then */etc/vfstab* "mount at boot" field will be ignored.

If mount points are specified, umount will only unmount those mount points. If none is specified, then umount will attempt to unmount all file systems in */etc/mnttab*, with the exception of certain system required file systems: */*, */usr*, */var*, */var/adm*, */var/run*, */proc*, */dev/fd* and */tmp*.

-f

Forcibly unmount a file system.

Without this option, umount does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (EIO).

-p

Print the list of mounted file systems in the */etc/vfstab* format. Must be the only option specified.

-v

Print the list of mounted file systems in verbose format. Must be the only option specified.

-V

Echo the complete command line, but do not execute the command. umount generates a command line by using the options and arguments provided by the user and adding to them information derived from */etc/mnttab*. This option should be used to verify and validate the command line.

generic_options

Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

-m

Mount the file system without making an entry in */etc/mnttab*.

-g

Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

-o

Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. (See *mount_ufs(1M)*)

-O
 Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy”.

-r
 Mount the file system read-only.

USAGE See `largefile(5)` for the description of the behavior of `mount` and `umount` when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

FILES `/etc/mnttab` mount table
`/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`
 LOCAL: The default partition for a command if no *FSType* is specified.
`/etc/vfstab` list of default parameters for each file system.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `mount_cachefs(1M)`, `mount_hsf(1M)`, `mount_nfs(1M)`, `mount_pcfs(1M)`, `mount_tmpfs(1M)`, `mount_ufs(1M)`, `mountall(1M)`, `umountall(1M)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`, `lofs(7FS)`, `pcfs(7FS)`

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mountall(1M)

NAME	mountall, umountall – mount, unmount multiple file systems												
SYNOPSIS	mountall [-F <i>FSType</i>] [-l -r] [<i>file_system_table</i>] umountall [-k] [-s] [-F <i>FSType</i>] [-l -r] umountall [-k] [-s] [-h <i>host</i>]												
DESCRIPTION	<p>mountall is used to mount file systems specified in a file system table. The file system table must be in <code>vfstab(4)</code> format. If no <i>file_system_table</i> is specified, <code>/etc/vfstab</code> will be used. If <code>'-'</code> is specified as <i>file_system_table</i>, mountall will read the file system table from the standard input. mountall only mounts those file systems with the <code>mount at boot</code> field set to <code>yes</code> in the <i>file_system_table</i>.</p> <p>Each file system which has an <code>fsckdev</code> entry specified in the file system table will be checked using <code>fsck(1M)</code> in order to determine if it may be safely mounted. If the file system does not appear mountable, it is fixed using <code>fsck</code> before the mount is attempted. File systems with a <code>'-'</code> entry in the <code>fsckdev</code> field will be mounted without first being checked.</p> <p>umountall causes all mounted file systems except <code>root</code>, <code>/usr</code>, <code>/var</code>, <code>/var/adm</code>, <code>/var/run</code>, <code>/proc</code>, and <code>/dev/fd</code> to be unmounted. If the <i>FSType</i> is specified, mountall and umountall limit their actions to the <i>FSType</i> specified. There is no guarantee that umountall will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.</p>												
OPTIONS	<table><tr><td>-F</td><td>Specify the <i>FSType</i> of the file system to be mounted or unmounted.</td></tr><tr><td>-h <i>host</i></td><td>Unmount all file systems listed in <code>/etc/mnttab</code> that are remote-mounted from host.</td></tr><tr><td>-k</td><td>Use the <code>fuser -k mount-point</code> command. See the <code>fuser(1M)</code> for details. The <code>-k</code> option sends the <code>SIGKILL</code> signal to each process using the file. As this option spawns kills for each process, the kill messages may not show up immediately. There is no guarantee that umountall will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.</td></tr><tr><td>-l</td><td>Limit the action to local file systems.</td></tr><tr><td>-r</td><td>Limit the action to remote file system types.</td></tr><tr><td>-s</td><td>Do not perform the <code>umount</code> operation in parallel.</td></tr></table>	-F	Specify the <i>FSType</i> of the file system to be mounted or unmounted.	-h <i>host</i>	Unmount all file systems listed in <code>/etc/mnttab</code> that are remote-mounted from host.	-k	Use the <code>fuser -k mount-point</code> command. See the <code>fuser(1M)</code> for details. The <code>-k</code> option sends the <code>SIGKILL</code> signal to each process using the file. As this option spawns kills for each process, the kill messages may not show up immediately. There is no guarantee that umountall will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.	-l	Limit the action to local file systems.	-r	Limit the action to remote file system types.	-s	Do not perform the <code>umount</code> operation in parallel.
-F	Specify the <i>FSType</i> of the file system to be mounted or unmounted.												
-h <i>host</i>	Unmount all file systems listed in <code>/etc/mnttab</code> that are remote-mounted from host.												
-k	Use the <code>fuser -k mount-point</code> command. See the <code>fuser(1M)</code> for details. The <code>-k</code> option sends the <code>SIGKILL</code> signal to each process using the file. As this option spawns kills for each process, the kill messages may not show up immediately. There is no guarantee that umountall will unmount <i>busy</i> filesystems, even if the <code>-k</code> option is specified.												
-l	Limit the action to local file systems.												
-r	Limit the action to remote file system types.												
-s	Do not perform the <code>umount</code> operation in parallel.												
FILES	<table><tr><td><code>/etc/mnttab</code></td><td>mounted file system table</td></tr><tr><td><code>/etc/vfstab</code></td><td>table of file system defaults</td></tr></table>	<code>/etc/mnttab</code>	mounted file system table	<code>/etc/vfstab</code>	table of file system defaults								
<code>/etc/mnttab</code>	mounted file system table

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fsck(1M)`, `fuser(1M)`, `mount(1M)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

DIAGNOSTICS No messages are printed if the file systems are mountable and clean.

Error and warning messages come from `fsck(1M)` and `mount(1M)`.

mount_cachefs(1M)

NAME	mount_cachefs – mount CacheFS file systems
SYNOPSIS	mount -F cachefs [<i>generic_options</i>] -o backfstype= <i>file_system_type</i> [<i>specific_options</i>] [-O] <i>special mount_point</i>
DESCRIPTION	The CacheFS-specific version of the mount command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process. For more information regarding back file systems, refer to the <i>System Administration Guide, Volume 1</i> .
OPTIONS	To mount a CacheFS file system, use the generic mount command with the -F option followed by the argument cachefs . See mount(1M) for a list of supported <i>generic_options</i> . -o <i>specific_options</i> Specify CacheFS file system specific options in a comma-separated list with no intervening spaces. acdirmax=<i>n</i> Specifies that cached attributes are held for no more than <i>n</i> seconds after directory update. After <i>n</i> seconds, all directory information is purged from the cache. The default value is 30 seconds. acdirmin=<i>n</i> Specifies that cached attributes are held for at least <i>n</i> seconds after directory update. After <i>n</i> seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds. acregmax=<i>n</i> Specifies that cached attributes are held for no more than <i>n</i> seconds after file modification. After <i>n</i> seconds, all file information is purged from the cache. The default value is 30 seconds. acregmin=<i>n</i> Specifies that cached attributes are held for at least <i>n</i> seconds after file modification. After <i>n</i> seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds. actimeo=<i>n</i> Sets acregmin , acregmax , acdirmin , and acdirmax to <i>n</i> . backfstype=<i>file_system_type</i> The file system type of the back file system (can be nfs or hsfs).

`backpath=path`

Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.

`cachedir=directory`

The name of the cache directory.

`cacheid=ID`

ID is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.

`demandconst`

Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the `-s` option of the `cfsadmin(1M)` command. This option is useful for back file systems that change infrequently, for example, `/usr/openwin`. `demandconst` and `noconst` are mutually exclusive.

`local-access`

Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access permissions. Do not use this argument with secure NFS.

`noconst`

Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify `noconst` only when you know that the back file system will not be modified. Trying to perform cache consistency check using `cfsadmin -s` will result in error. `demandconst` and `noconst` are mutually exclusive.

`purge`

Purge any cached information for the specified file system.

`ro | rw`

Read-only or read-write (default).

`suid | nosuid`

Allow (default) or disallow `setuid` execution.

`write-around | non-shared`

Write modes for CacheFS. The `write-around` mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the `non-shared` mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

`-O`

Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: `mount -F cachefs: mount failed Device busy`.

mount_cachefs(1M)

EXAMPLES | **EXAMPLE 1** CacheFS-mounting a file system.

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,  
             cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the mount command is executed:

```
server1:/user2  /usr/abc      nfs  
/usr/abc       /cache1/xyz    cachefs      backfstype=nfs
```

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

SEE ALSO | `cfadmin(1M)`, `fsck_cachefs(1M)`, `mount(1M)`, `attributes(5)` *System Administration Guide, Volume 1*

NAME	mountd – server for NFS mount requests and NFS access checks				
SYNOPSIS	<code>/usr/lib/nfs/mountd [-v] [-r]</code>				
DESCRIPTION	<p>mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file <code>/etc/dfs/sharetab</code> to determine which file systems are available for mounting by which remote machines. See <code>sharetab(4)</code>. <code>nfsd</code> running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the <code>remoted</code> procedure call from the client. See <code>share_nfs(1M)</code>.</p> <p>The command also provides information as to what file systems are mounted by which clients. This information can be printed using the <code>showmount(1M)</code> command.</p> <p>The mountd daemon is automatically invoked in run level 3.</p> <p>Only super user can run the mountd daemon.</p>				
OPTIONS	<p><code>-v</code> Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.</p> <p><code>-r</code> Reject mount requests from clients. Clients that have file systems mounted will not be affected.</p>				
FILES	<code>/etc/dfs/sharetab</code> shared file system table				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>nfsd(1M)</code> , <code>share_nfs(1M)</code> , <code>showmount(1M)</code> , <code>sharetab(4)</code> , <code>attributes(5)</code>				
NOTES	<p>If <code>nfsd</code> is running, mountd must also be running in order to be assured that the NFS server can respond to requests, otherwise, the NFS service can hang.</p> <p>Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.</p>				

mount_hsfS(1M)

NAME	mount_hsfS – mount hsfS file systems
SYNOPSIS	mount -F hsfS [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F hsfS [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	<p>mount attaches a High Sierra file system (hsfS) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>FSType-specific_options</i>; see mount(1M) for more details.</p> <p>If the file system being mounted contains Rock Ridge extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.</p>
OPTIONS	<p><i>generic_options</i> See mount(1M) for the list of supported options.</p> <p>-o Specify hsfS file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:</p> <p>global noglobal If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal.</p> <p>ro Mount the file system read-only. This option is required.</p> <p>nrr no Rock Ridge: if Rock Ridge extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system.</p> <p>notraildot File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying notraildot makes it optional to specify the trailing dot to access a file whose name lacks an extension.</p> <p><i>Exceptions:</i> This option is effective only on file systems for which Rock Ridge extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the nrr option. If Rock Ridge extensions are active, hsfS quietly ignores this option.</p>

nomaplcas

File names on High Sierra cdroms with no Rock Ridge extensions present should be uppercase characters only. By default, `hfs` maps file names read from a non-Rock Ridge disk to all lowercase characters. `nomaplcas` turns off this mapping. The exceptions for `notraildot` discussed above apply to `nomaplcas`.

nosuid

By default the file system is mounted with `setuid` execution allowed. Specifying `nosuid` causes the file system to be mounted with `setuid` execution disallowed.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error `device busy`.

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_nfs(1M)

NAME	mount_nfs – mount remote NFS resources
SYNOPSIS	mount [-F nfs] [generic_options] [-o specific_options] [-O] resource mount [-F nfs] [generic_options] [-o specific_options] [-O] mount_point mount [-F nfs] [generic_options] [-o specific_options] [-O] resource mount_point
DESCRIPTION	<p>The mount utility attaches a named <i>resource</i> to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, the contents remain hidden until the <i>resource</i> is once again unmounted.</p> <p>If the resource is listed in the <code>/etc/vfstab</code> file, the command line can specify either <i>resource</i> or <i>mount_point</i>, and mount will consult <code>/etc/vfstab</code> for more information. If the -F option is omitted, mount takes the file system type from <code>/etc/vfstab</code>.</p> <p>If the resource is not listed in the <code>/etc/vfstab</code> file, then the command line must specify both the <i>resource</i> and the <i>mount_point</i>.</p> <p>A named <i>resource</i> can have one of the following formats:</p> <p><i>host:pathname</i> Where <i>host</i> is the name of the NFS server host, and <i>pathname</i> is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this will be the case.</p> <p><i>nfs://host[:port]/pathname</i> This is an NFS URL and follows the standard convention for NFS URLs as described in <i>Internet RFC 2225 — NFS URL Scheme</i>. See the discussion of URL's and the public option under NFS FILE SYSTEMS below for a more detailed discussion.</p> <p>A comma-separated list of <i>host:pathname</i> and/or <i>nfs://host[:port]/pathname</i> resources See the discussion of Replicated file systems and failover under NFS FILE SYSTEMS below for a more detailed discussion.</p> <p>A comma-separated list of hosts followed by a <i>:pathname</i> suffix See the discussion of Replicated file systems and failover under NFS FILE SYSTEMS below for a more detailed discussion</p> <p>mount maintains a table of mounted file systems in <code>/etc/mnttab</code>, described in <code>mnttab(4)</code>.</p>
OPTIONS	See <code>mount(1M)</code> for the list of supported <i>generic_options</i> .
	<i>-o specific_options</i> Set file system specific options according to a comma-separated list with no intervening spaces.
	<i>acdirmax=n</i> Hold cached attributes for no more than <i>n</i> seconds after directory update. The default value is 60.

`acdirmin=n`

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

`acregmax=n`

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

`acregmin=n`

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

`actimeo=n`

Set *min* and *max* times for regular files and directories to *n* seconds.

`bg | fg`

If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

`grpuid`

By default, the GID associated with a newly created file will obey the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior may be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see `open(2)` and `mkdir(2)`). Files created on file systems that are mounted with the `grpuid` option will obey BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

`hard | soft`

Continue to retry requests until the server responds (`hard`) or give up and return an error (`soft`). The default value is `hard`.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is `intr`, which makes it possible for clients to interrupt applications that may be waiting for a remote mount.

`noac`

Suppress data and attribute caching.

mount_nfs(1M)

nocto

Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When `-nocto` is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system will be made from only one client and only that client. Under such a condition, the effect of `-nocto` can be a slight performance gain.

port=*n*

The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a `port` number, then the `port` number in the option and in the URL must be the same.

posix

Request POSIX.1 semantics for the file system. Requires a mount Version 2 `mountd(1M)` on the server. See `standards(5)` for information regarding POSIX.

proto=<*netid*>

<*netid*> is a value of `network_id` field from entry in the `/etc/netconfig` file. By default, the transport protocol used for the NFS mount will be first available connection oriented transport supported on both the client and the server. If no connection oriented transport is found, then the first available connectionless transport is used. This default behavior can be overridden with the `proto=<netid>` option.

public

The `public` option forces the use of the public file handle when connecting to the NFS server. The resource specified may or may not have an NFS URL. See the discussion of URL's and the `public`

mount_nfs(1M)

option under NFS FILE SYSTEMS below for a more detailed discussion.

quota | noquota

Enable or prevent `quota(1M)` to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas will still be checked for operations on this file system.

remount

Remounts a read-only file system as read-write (using the `rw` option). This option cannot be used with other `-o` options, and this option works only on currently mounted read-only file systems.

retrans=*n*

Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport will perform retransmissions on behalf of NFS.

retry=*n*

The number of times to retry the mount operation. The default for the `mount` command is 10000.

The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary “server not responding” errors.

ro | rw

resource is mounted read-only or read-write. The default is `rw`.

rsize=*n*

Set the read buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

sec=*mode*

Set the security *mode* for NFS transactions. If `sec=` is not specified, then the default action is to use `AUTH_SYS` over NFS Version 2 mounts, or to negotiate a *mode* over NFS Version 3 mounts. NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The

mount_nfs(1M)

client will pick the first mode in the array that is supported on the client. Only one mode can be specified with the `sec=` option. See `nfssec(5)` for the available *mode* options.

`secure`

This option has been deprecated in favor of the `sec=dh` option.

`suid | nosuid`

Allow or disallow `setuid` execution. The default is `suid`.

`timeo=n`

Set the NFS timeout to *n* tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports.

`vers=<NFS version number>`

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. If the NFS server does not support NFS Version 3 protocol, then the NFS mount will use NFS Version 2 protocol.

`wsiz=n`

Set the write buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy."

NFS FILE SYSTEMS

Background versus Foreground

File systems mounted with the `bg` option indicate that mount is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n`

option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems may incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

Authenticated Requests

The server may require authenticated NFS requests from the client. Either `sec=dh` or `sec=krb4` authentication may be required. See `nfssec(5)`.

URLs and the public option

If the `public` option is specified, or if the `resource` includes an NFS URL, `mount` will attempt to connect to the server using the public file handle lookup protocol. See *Internet RFC 2054 — WebNFS Client Specification*. If the server supports the public file handle, the attempt is successful; `mount` will not need to contact the server's `rpcbind(1M)`, and the `mountd(1M)` daemons to get the port number of the mount server and the initial file handle of `pathname`, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as `NFS_PORT`, then this enables NFS operations through the firewall. The `public` option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

	resource style	
	<i>host:pathname</i>	NFS URL
public option	+ force public file handle and fail mount if not supported. + use Native paths	+ force public file handle and fail mount if not supported. + use Canonical paths
default	+ use MOUNT protocol	+ try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.

A *Native path* is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A *Canonical path* is a path name that is interpreted according to the URL rules. See *Internet RFC 1738 — Uniform Resource Locators (URL)*. Also, see **EXAMPLES for uses of *Native* and *Canonical* paths.**

Replicated file systems and failover

`resource` can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is

mount_nfs(1M)

also recommended that they be created by a utility such as `rdist(1)`. The file systems may be specified either with a comma-separated list of `host:/pathname` entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover will use the next alternate server to access files. If the read-only option is not chosen, replication will be disabled. File access will block on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times may be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting `actimeo=n` sets flush time to *n* seconds for both regular files and directories.

Setting `actimeo=0` disables attribute caching on the client. This means that every reference to attributes will be satisfied directly from the server though file data will still be cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the `noac` option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application will be written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (`mmap(2)`) will not be written directly to this server.

EXAMPLES

EXAMPLE 1 Mounting An NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

EXAMPLE 2 Mounting An NFS File System Read-Only With No Suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

EXAMPLE 3 Mounting An NFS File System Over Version 2, With The UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

EXAMPLE 3 Mounting An NFS File System Over Version 2, With The UDP Transport
(Continued)

EXAMPLE 4 Mounting An NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7-bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

EXAMPLE 6 Mounting An NFS File System Using A Native Path

To mount an NFS file system using a native path (where the server uses colons (":") as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

EXAMPLE 7 Mounting an NFS file system using AUTH_KERB authentication.

To mount an NFS file system using AUTH_KERB authentication:

```
example# mount -o sec=krb4 serv:/usr/src /usr/src
```

EXAMPLE 8 Mounting a replicated set of NFS file systems with the same pathnames.

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man
```

EXAMPLE 9 Mounting a replicated set of NFS file systems with different pathnames.

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man
```

Internet RFC 1738— Uniform Resource Locators (URL)

Internet RFC 2054 — WebNFS Client Specification

Internet RFC 2225 — NFS URL Scheme

NOTES An NFS server should not attempt to mount its own file systems. See `lofs(7FS)`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers*, rather than being mounted on top of the symbolic link itself.

SunOS 4.X used the `biod` maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.X made `biod` obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

NAME	mount_pcfs – mount pcfs file systems				
SYNOPSIS	<pre>mount -F pcfs [generic_options] [-o FSType-specific_options] special mount_point mount -F pcfs [generic_options] [-o FSType-specific_options] special mount_point</pre>				
DESCRIPTION	<p>mount attaches an MS-DOS file system (<code>pcfs</code>) to the file system hierarchy at the <code>mount_point</code>, which is the pathname of a directory. If <code>mount_point</code> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with <code>special</code> or <code>mount_point</code> as the only arguments, mount will search <code>/etc/vfstab</code> to fill in the missing arguments, including the <code>FSType-specific_options</code>; see <code>mount(1M)</code> for more details.</p> <p>The <code>special</code> argument can be one of two special device file types:</p> <ul style="list-style-type: none"> ■ A floppy disk, such as <code>/dev/diskette0</code> or <code>/dev/diskette1</code>. ■ A DOS logical drive on a hard disk expressed as <code>device-name:logical-drive</code>, where <code>device-name</code> specifies the special block device-file for the whole disk and <code>logical-drive</code> is either a drive letter (c through z) or a drive number (1 through 24). Examples are <code>/dev/dsk/c0t0d0p0:c</code> and <code>/dev/dsk/c0t0d0p0:1</code>. <p>The <code>special</code> device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.</p>				
OPTIONS	<p><code>generic_options</code> See <code>mount(1M)</code> for the list of supported options.</p> <p><code>-o</code> Specify <code>pcfs</code> file system specific options. The following options are available:</p> <p><code>rw ro</code> Mount the file system read/write or read-only. The default is <code>rw</code>.</p> <p><code>foldcase nofoldcase</code> Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of <code>pcfs</code>. The default is <code>nofoldcase</code>.</p>

NOTES | If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

NAME	mount_s5fs – mount s5 file systems						
SYNOPSIS	mount -F s5fs [-r] [-o <i>specific_options</i>] <i>special</i> <i>mount_point</i> mount -F s5fs [-r] [-o <i>specific_options</i>] <i>special</i> <i>mount_point</i>						
DESCRIPTION	mount attaches a s5 file system (a System V file system used by PC versions of UNIX) to the file system hierarchy at the <i>mount_point</i> , which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>specific_options</i> . See mount(1M). If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i> , the default is rw.						
OPTIONS	-o <i>specific_options</i> Specify s5 file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: remount Remounts a read-only file system as read-write (using the rw option). This option cannot be used with other -o options, and this option works only on currently mounted read-only file systems. ro rw Read-only or read-write. The default is rw. suid nosuid Allow or disallow setuid execution. The default is suid. -r Mount the file system read-only.						
FILES	/etc/mnttab table of mounted file systems /etc/vfstab list of default parameters for each file system						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

NOTES | If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

NAME	mount_tmpfs – mount tmpfs file systems				
SYNOPSIS	mount [-F tmpfs] [-o size= sz] [-O] <i>special mount_point</i>				
DESCRIPTION	<p>tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.</p> <p>mount attaches a tmpfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values.</p> <p>The <i>special</i> argument is usually specified as <i>swap</i> but is in fact disregarded and assumed to be the virtual memory resources within the system.</p>				
OPTIONS	<p>-o size=sz The <i>sz</i> argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.</p> <p>-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error <i>device busy</i>.</p>				
FILES	/etc/mnttab table of mounted file systems				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	mount(1M) , mkdir(2) , mount(2) , open(2) , umount(2) , mnttab(4) , attributes(5) , tmpfs(7FS)				
NOTES	If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.				

mount_udfs(1M)

NAME	mount_udfs – mount a udfs file system
SYNOPSIS	mount -F udfs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i> mount -F udfs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	<p>The mount utility attaches a <i>udfs</i> file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with either <i>special</i> or <i>mount_point</i> as the only arguments, mount searches <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>specific_options</i>. See mount(1M).</p> <p>If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <i>rw</i>.</p> <p>If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.</p>
OPTIONS	<p>See mount(1M) for the list of supported <i>generic_options</i>.</p> <p>The following options are supported:</p> <ul style="list-style-type: none">-o <i>specific_options</i> Specify <i>udfs</i> file system specific options in a comma-separated list with no intervening spaces. The following <i>specific_options</i> are available:<ul style="list-style-type: none">m Mount the file system without making an entry in <i>/etc/mnttab</i>.nosuid Mount the file system with <i>setuid</i> execution disallowed. You can also use <i>nosuid</i> to disallow <i>setuid</i> when mounting devices. By default, the file system is mounted with <i>setuid</i> execution allowed.remount Remount the file system as read-write. The option is used in conjunction with the <i>rw</i> option. A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted or if the file system is mounted as <i>rw</i>.rw ro Read-write (<i>rw</i>) or read-only (<i>ro</i>). <i>rw</i> is the default.

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error `device busy`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWudf

SEE ALSO `fsck(1M)`, `fsck_udfs(1M)`, `mount(1M)`, `mountall(1M)`, `mount(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

DIAGNOSTICS `not super user`
The command is run by a non-root user. Run as root.

`no such device`
The device name specified does not exist.

`not a directory`
The specified mount point is not a directory.

`is not an udfs file system`
The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.

`is already mounted`
The specified device is already in use.

`not a block device`
The device specified is not a block device. Use block device to mount.

`write-protected`
The device is read-only.

`is corrupted. needs checking`
The file system is in an inconsistent state. Run `fsck`.

NOTES Copy-protected files can be stored on DVD-ROM media using UDF. Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

mount_ufs(1M)

NAME	mount_ufs – mount ufs file systems
SYNOPSIS	mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i>
DESCRIPTION	<p>The mount utility attaches a <i>ufs</i> file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted.</p> <p>If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>specific_options</i>. See mount(1M).</p> <p>If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <i>rw</i>.</p> <p>If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.</p>
OPTIONS	<p>See mount(1M) for the list of supported <i>generic_options</i>.</p> <p>The following options are supported:</p> <ul style="list-style-type: none">-o <i>specific_options</i> Specify <i>ufs</i> file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:<ul style="list-style-type: none">noatime By default, the file system is mounted with normal access time (<i>atime</i>) recording. If noatime is specified, the file system will ignore access time updates on files, except when they coincide with updates to the <i>ctime</i> or <i>mtime</i>. See stat(2). This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool). noatime turns off access time recording regardless of dfratime or nodfratime.dfratime nodfratime By default, writing access time updates to the disk may be deferred (dfratime) for the file system until the disk is accessed for a reason other than updating access times. nodfratime disables this behavior.forcedirectio noforcedirectio If forcedirectio is specified and supported by the file system, then for the duration of the mount forced direct I/O will be used. If the filesystem is mounted using forcedirectio, then data is transferred directly between user address space and the disk. If the filesystem is mounted using noforcedirectio, then data is buffered in kernel address space when data is transferred between user address space and the disk. forcedirectio is a

performance option that benefits only from large sequential data transfers. The default behavior is `noForcedirectio`.

`global | noglobal`

If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles | nolargefiles`

If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, mount will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging | nologging`

If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore eliminating the need to run `fsck`. And, because `fsck` can be bypassed, logging reduces the time required to reboot a system if it crashes, or after an unclean halt. The default behavior is `nologging`.

The log is allocated from free blocks on the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes. Logging can be enabled on any UFS, including root (/). The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

`m`

Mount the file system without making an entry in `/etc/mnttab`.

mount_ufs(1M)

onerror=*action*

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as *panic*, *lock*, or *umount*. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is *panic*.

quota

Quotas are turned on for the file system.

remount

Remounts a read-only file system as read-write (using the *rw* option). This option can be used only in conjunction with the *f*, *logging|nologging*, *m*, and *noatime* options. This option works only on currently mounted read-only file systems.

rq

Read-write with quotas turned on. Equivalent to *rw*, *quota*.

ro | rw

Read-only or read-write. Default is *rw*.

suid | nosuid

Allow or disallow *setuid* execution. The default is *suid*. This option can also be used when mounting devices.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

FILES /etc/mnttab table of mounted file systems
/etc/vfstab list of default parameters for each file system

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *fsck(1M)*, *fsck_ufs(1M)*, *mount(1M)*, *mountall(1M)*, *mount(2)*, *stat(2)*, *mnttab(4)*, *vfstab(4)*, *attributes(5)*, *largefile(5)*

NOTES Since the root (/) file system is mounted read-only by the kernel during the boot process, only the *remount* option (and options that can be used in conjunction with *remount*) affect the root (/) entry in the */etc/vfstab* file.

NAME	mount_xmemfs – mount xmemfs file systems
SYNOPSIS	mount -F xmemfs [<i>generic_options</i>] -o[<i>largebsize</i> ,] <i>size=sz</i> [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	<p>xmemfs is an extended memory file system which provides file system semantics to manage and access large amounts of physical memory which can exceed 4 GB in size.</p> <p>mount attaches a xmemfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (<i>mode</i>, <i>owner</i>, and <i>group</i>) of the root of the xmemfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values.</p> <p>The special argument is not currently used by xmemfs but a placeholder, (such as <i>xmem</i>), needs to be specified nevertheless.</p>
OPTIONS	<p>See mount(1M) for the list of supported <i>generic_options</i>.</p> <p><i>-ospecific_options</i></p> <p>Specify xmemfs file system specific options in a comma-separated list with <i>no intervening spaces</i>. If invalid options are specified, a warning message is printed and the invalid options are ignored.</p> <p>The <i>size=sz specific option</i> is required.</p> <p>The following options are available:</p> <p><i>size=sz</i> The <i>sz</i> argument specifies the desired size of this particular xmemfs file system. If the <i>sz</i> argument has a <i>k</i> suffix, the number is interpreted as kilobytes. An <i>m</i> suffix is interpreted as megabytes and <i>g</i> is interpreted as gigabytes. A <i>sz</i> specified with no suffix is interpreted as bytes.</p> <p>In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical <i>pagesize</i> of the system or to the large page size if <i>largebsize</i> is specified.</p> <p><i>largebsize</i> This <i>specific_option</i> is required.</p> <p>If <i>largebsize</i> is specified, xmemfs uses the large memory page size as the file system block</p>

mount_xmemfs(1M)

size. On IA32, the large memory page size with mmu36 which supports PAE (Physical Address Extension) is 2 MB. The large memory page size without mmu36/PAE is 4 MB. If there is no large page support, the file system block size is PAGESIZE.

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.

FILES /etc/mnttab table of mounted file systems

Architecture	i386
Interface Stability	Evolving

SEE ALSO mount(1M), mount(2), mkdir(2), open(2), umount(2), mnttab(4), attributes(5), xmemfs(7FS)

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

The only file types allowed on xmemfs are directories and regular files. The execution of object files resident in xmemfs is not supported. Execution is prevented by not allowing users to set execute permissions on regular files.

NAME	mpstat – report per-processor statistics																																		
SYNOPSIS	<code>/usr/bin/mpstat [-p -P <i>set</i>] [<i>interval</i> [<i>count</i>]]</code>																																		
DESCRIPTION	<p>mpstat reports per-processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot; each subsequent table summarizes activity for the preceding interval. All values are rates (events per second) unless otherwise noted.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. mpstat reports this as <code>State change</code>.</p> <p>mpstat reports the following information:</p> <table border="0"> <tr><td>cpu</td><td>processor ID</td></tr> <tr><td>minf</td><td>minor faults</td></tr> <tr><td>mjf</td><td>major faults</td></tr> <tr><td>xcal</td><td>inter-processor cross-calls</td></tr> <tr><td>intr</td><td>interrupts</td></tr> <tr><td>ithr</td><td>interrupts as threads (not counting clock interrupt)</td></tr> <tr><td>csw</td><td>context switches</td></tr> <tr><td>icsw</td><td>involuntary context switches</td></tr> <tr><td>migr</td><td>thread migrations (to another processor)</td></tr> <tr><td>smtx</td><td>spins on mutexes (lock not acquired on first try)</td></tr> <tr><td>srw</td><td>spins on readers/writer locks (lock not acquired on first try)</td></tr> <tr><td>syscl</td><td>system calls</td></tr> <tr><td>usr</td><td>percent user time</td></tr> <tr><td>sys</td><td>percent system time</td></tr> <tr><td>wt</td><td>percent wait time</td></tr> <tr><td>idl</td><td>percent idle time</td></tr> </table> <p>For the <code>-p</code> option, mpstat also reports the following information:</p> <table border="0"> <tr><td>set</td><td>processor set membership of the CPU</td></tr> </table>	cpu	processor ID	minf	minor faults	mjf	major faults	xcal	inter-processor cross-calls	intr	interrupts	ithr	interrupts as threads (not counting clock interrupt)	csw	context switches	icsw	involuntary context switches	migr	thread migrations (to another processor)	smtx	spins on mutexes (lock not acquired on first try)	srw	spins on readers/writer locks (lock not acquired on first try)	syscl	system calls	usr	percent user time	sys	percent system time	wt	percent wait time	idl	percent idle time	set	processor set membership of the CPU

NOTES The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

NAME	msgid – generate message IDs				
SYNOPSIS	<code>/usr/sbin/msgid</code>				
DESCRIPTION	<p>The <code>msgid</code> utility generates message IDs.</p> <p>A message ID is a numeric identifier that, with a high probability, uniquely identifies a message. The probability of two distinct messages having the same ID is about one in a million. Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by <code>STRLOG_MAKE_MSGID()</code> as defined in <code><sys/strlog.h></code>.</p> <p><code>syslogd(1M)</code> is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by <code>syslogd(1M)</code> includes the message ID. The message ID is intended to serve as a small, language-independent identifier.</p>				
EXAMPLES	<p>EXAMPLE 1 Using the <code>msgid</code> command to generate a message ID</p> <p>The following example uses the <code>msgid</code> command to generate a message ID for the <code>echo</code> command.</p> <pre>example# echo hello msgid 205790 hello</pre> <p>EXAMPLE 2 Using the <code>msgid</code> command to generate a message catalog</p> <p>The following example uses the <code>msgid</code> command to enumerate all of the messages in the binary <code>ufs</code>, to generate a message catalog.</p> <pre>example# strings /kernel/fs/ufs msgid 137713 free: freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s 567420 iallocg: block not in mapfs = %s 845546 alloc: %s: file system full ...</pre>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

mvmkdir(1M)

NAME	mvmkdir – move a directory				
SYNOPSIS	<code>/usr/sbin/mvmkdir</code> <i>dirname</i> <i>name</i>				
DESCRIPTION	<p>mvmkdir moves directories within a file system. <i>dirname</i> must be a directory. If <i>name</i> does not exist, it will be created as a directory. If <i>name</i> does exist, and is a directory, <i>dirname</i> will be created as <i>name/dirname</i>. <i>dirname</i> and <i>name</i> may not be on the same path; that is, one may not be subordinate to the other. For example:</p> <pre>example% mvmkdir x/y x/z</pre> <p>is legal, but</p> <pre>example% mvmkdir x/y x/y/z</pre> <p>is not.</p>				
OPERANDS	<table><tr><td><i>dirname</i></td><td>The name of the directory that is to be moved to another directory in the filesystem.</td></tr><tr><td><i>name</i></td><td>The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i>.</td></tr></table>	<i>dirname</i>	The name of the directory that is to be moved to another directory in the filesystem.	<i>name</i>	The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> .
<i>dirname</i>	The name of the directory that is to be moved to another directory in the filesystem.				
<i>name</i>	The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> .				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>mvmkdir</code> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).				
EXIT STATUS	<table><tr><td>0</td><td>Successful operation.</td></tr><tr><td>>0</td><td>Operation failed.</td></tr></table>	0	Successful operation.	>0	Operation failed.
0	Successful operation.				
>0	Operation failed.

NAME named-bootconf – convert name server configuration files

SYNOPSIS `named-bootconf`

DESCRIPTION `named-bootconf` converts named configuration files from BIND 4 format to BIND 8 format.

Comments from the source file will not always appear at the appropriate place in the target file.

EXAMPLES **EXAMPLE 1** Using `named-bootconf`

The following command shows conversion of the `named.boot` file:

```
example# named-bootconf < named.boot > named.conf
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard BIND 8.2.2

SEE ALSO `in.named(1M)`, `named.conf(4)`, `attributes(5)`

named-xfer(1M)

NAME named-xfer – ancillary agent for inbound zone transfers

SYNOPSIS **named-xfer** -z *zone_to_transfer* -f *db_file* -s *serial_no* [-d *debuglevel*]
 [-l *debug_log_file*] [-t *trace_file*] [-p *port#*] [-S] *nameserver...*

DESCRIPTION The named-xfer program is an ancillary program executed by in.named to perform an inbound zone transfer. It is rarely executed directly, and only by system administrators who are trying to debug a zone transfer problem. See RFC’s 1033, 1034, and 1035 for more information on the Internet name-domain system.

OPTIONS

- z Specifies the name of the zone to be transferred.
- f Specifies the name of the file into which the zone should be dumped when it is received from the primary server.
- s Specifies the serial number of the current copy of this zone. If the SOA RR from the primary server does not have a serial number higher than this, the transfer will be aborted.
- d Print debugging information. A number after the “d” determines the level of messages printed.
- l Specifies a log file for debugging messages. The default is system-dependent but is usually in */var/tmp* or */usr/tmp*. Note that this only applies if -d is also specified.
- t Specifies a trace file which will contain a protocol trace of the zone transfer. This is probably only of interest to those debugging the name server itself.
- p Use a different port number. The default is the standard port number as returned by *getservbyname(3SOCKET)* for service “domain”.
- S Perform a restricted transfer of only the SOA, NS records and glue A records for the zone. The SOA record will not be loaded by named but will be used to determine when to verify the NS records. See the “stubs” directive in *in.named(1M)* for more information.

Additional arguments are taken as name server addresses in so-called “dotted-quad” syntax only; no host names are allowed. At least one address must be specified. If the first one fails to transfer successfully, the additional addresses will be tried in the order given.

Name Server Operations Guide for BIND

ncaconfd(1M)

NAME ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon
SYNOPSIS /usr/lib/inet/ncaconfd

DESCRIPTION Use the ncaconfd utility to set up NCA on a system. At boot time, the ncakmod initialization script reads in nca.if(4) to determine on which interface(s) NCA should run. ncaconfd then sets up the interface.

ncaconfd also operates as a daemon if the nca_active key is set to enabled in ncakmod.conf(4) file. In this case, ncaconfd will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

FILES /etc/nca/ncakmod.conf

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWncau

SEE ALSO nca(1), ncakmod(1), nca.if(4), ncakmod.conf(4), attributes(5)

NAME	ncad – Solaris Network Cache and Accelerator (NCA) door server daemon				
SYNOPSIS	<code>/usr/lib/inet/ncad</code>				
DESCRIPTION	<p>ncad is a utility used to increase web server performance when the Solaris Network Cache and Accelerator (NCA) feature is enabled. ncad implements a Solaris doors server, which is the interface between the NCA kernel module and a web server.</p> <p>If the NCA feature is enabled, ncad is started at system boot by the initialization script. To enable NCA, the user must modify the ncad_status field in the ncakmod.conf file from the default value of disabled to enabled. See ncakmod.conf(4).</p> <p>If a web server includes a native port of the Solaris doors server, and you do not want to use the ncad utility, the daemon must be disabled during system boot. Modify the ncad_status field in the ncakmod.conf file from enabled to disabled.</p>

ncheck(1M)

NAME	ncheck – generate a list of path names versus i-numbers
SYNOPSIS	ncheck [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [<i>special...</i>]
DESCRIPTION	ncheck with no options generates a path-name versus i-number list of all files on <i>special</i> . If <i>special</i> is not specified on the command line the list is generated for all <i>specials</i> in /etc/vfstab which have a numeric <i>fsckpass</i> . <i>special</i> is a block special device on which the file system exists.
OPTIONS	<p>-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric <i>fsckpass</i> field and an <i>fsckdev</i> that matches <i>special</i>.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.</p> <p><i>generic_options</i> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available:</p> <ul style="list-style-type: none"> -i <i>i-list</i> Limit the report to the files on the <i>i-list</i> that follows. The <i>i-list</i> must be separated by commas with no intervening spaces. -a Print the names "." and "." which are ordinarily suppressed. -s Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy. <p>-o Specify <i>FSType-specific_options</i> in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
FILES	/etc/vfstab list of default parameters for each file system
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *vfstab(4)*, *attributes(5)*, *largefile(5)* Manual pages for the FSType-specific modules of ncheck

NOTES This command may not be supported for all *FSTypes*.

ncheck_ufs(1M)

- NAME** ncheck_ufs – generate pathnames versus i-numbers for ufs file systems
- SYNOPSIS** **ncheck** -F ufs [*generic_options*] [-o m] [*special...*]
- DESCRIPTION** ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on *special*. Names of directory files are followed by '/.'.
- OPTIONS** See ncheck(1M) for the list of *generic_options* supported.
- o Specify ufs file system specific options. The available option is:
 - m Print mode information.
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

- SEE ALSO** ff(1M), ncheck(1M), attributes(5)
- DIAGNOSTICS** When the file system structure is improper, '??' denotes the "parent" of a parentless file and a pathname beginning with './..' denotes a loop.

NAME	ndc – name daemon control program
SYNOPSIS	ndc [-c <i>channel</i>] [-l <i>localsock</i>] [-p <i>pidfile</i>] [-d] [-q] [-s] [-t] [<i>command</i>]
DESCRIPTION	System administrators use the <i>ndc</i> utility to control the operation of a name server. If the system administrator fails to list a command, <i>ndc</i> will prompt for one until it reads EOF.
OPTIONS	<p>The <i>ndc</i> command supports the following options:</p> <p>-c <i>channel</i> Specify the rendezvous point for the control channel. The default value for <i>channel</i> is <i>/var/run/ndc</i>, a UNIX domain socket that is also the server's default control channel. If the desired control channel is a TCP/IP socket, then the format for the <i>channel</i> argument is <i>ipaddr/port</i>. For example, a value of <i>127.0.0.1/54</i> would be TCP port 54 on the local host.</p> <p>-d Turn on debugging mode. This option is mainly of interest to developers.</p> <p>-l <i>localsock</i> Bind the client side of the control channel to a specific address. Servers can be configured to reject connections that do not come from specific addresses. If the desired control channel is a TCP/IP socket, then the format for the <i>localsock</i> argument is <i>ipaddr/port</i>.</p> <p>-p <i>pidfile</i> Use for backwards compatibility with older name servers. It enables <i>ndc</i> to use UNIX signals for control communications. Optional with modern name servers, this capability may not be supported in future releases. The command set that is available is narrower when the signal interface is used. A likely value for the <i>pidfile</i> argument is <i>/var/run/named.pid</i>.</p> <p>-q Suppress prompt and result text.</p> <p>-s Suppress non-fatal error announcements.</p> <p>-t Turn on protocol and system tracing. Use this option in installation debugging.</p>
COMMANDS	<p>The following commands are built into the <i>ndc</i> utility. The full set of commands that the name server supports is dynamic. Use the <i>help</i> command for information on the available commands .</p> <p><i>/help</i> Show help information for built in commands.</p> <p><i>/exit</i> Exit from <i>ndc</i> command interpreter.</p> <p><i>/trace</i> Toggle protocol and system tracing on and off. See -t.</p> <p><i>/debug</i> Toggle debugging mode on and off. See -d.</p> <p><i>/quiet</i> Toggle prompt and result information on and off. See -q.</p>

ndc(1M)

/silent Toggle announcement of non-fatal errors on and off.
See -s.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard, BIND 8.2.2

SEE ALSO `in.named(1M)`, `execvp(2)`, `attributes(5)`

NOTES When the `ndc` utility is running in *pidfile* mode, pass any arguments to start and restart commands to the new name server on the command line. If the `ndc` utility is running in *channel* mode, there is no start command, and the restart command just tells the name server to `execvp(2)` itself.

NAME | `ndd` – get and set driver configuration parameters

SYNOPSIS | `ndd [-set] driver parameter [value]`

DESCRIPTION | `ndd` gets and sets selected configuration parameters in some kernel drivers. Currently, `ndd` only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using `ndd`. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

If the `-set` option is omitted, `ndd` queries the named *driver*, retrieves the value associated with the specified *parameter*, and prints it. If the `-set` option is given, `ndd` passes *value*, which must be specified, down to the named *driver* which assigns it to the named *parameter*.

By convention, drivers that support `ndd` also support a special read-only *parameter* named “?” which can be used to list the parameters supported by the driver.

EXAMPLES | **EXAMPLE 1** Getting Parameters Supported By The TCP Driver

To see which parameters are supported by the TCP driver, use the following command:

```
example% ndd /dev/tcp \?
```

The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter *ip_forwarding* in the dual stack IP driver to zero. This disables IPv4 packet forwarding.

```
example% ndd -set /dev/ip ip_forwarding 0
```

Similarly, in order to disable IPv6 packet forwarding, the value of parameter *ip6_forwarding*

```
example% ndd -set /dev/ip ip6_forwarding 0
```

To view the current IPv4 forwarding table, use the following command:

```
example% ndd /dev/ip ipv4_ire_status
```

To view the current IPv6 forwarding table, use the following command:

```
example% ndd /dev/ip ipv6_ire_status
```

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

ndd(1M)

SEE ALSO | [ioctl\(2\)](#), [attributes\(5\)](#), [arp\(7P\)](#), [ip\(7P\)](#), [ip6\(7P\)](#), [tcp\(7P\)](#), [udp\(7P\)](#)

NOTES | The parameters supported by each driver may change from release to release. Like programs that read `/dev/kmem`, user programs or shell scripts that execute `ndd` should be prepared for parameter names to change.

The `ioctl()` command that `ndd` uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many `ndd` parameters make sense only if you understand how the driver is implemented.

NAME	netstat – show network status														
SYNOPSIS	<pre> netstat [-anv] [-f <i>address_family</i>] netstat [-g -p -s] [-n] [-f <i>address_family</i>] [-P <i>protocol</i>] netstat -m netstat -i [-I <i>interface</i>] [-an] [-f <i>address_family</i>] [<i>interval</i>] netstat -r [-anv] [-f <i>address_family</i>] netstat -M [-ns] [-f <i>address_family</i>] netstat -D [-I <i>interface</i>] [-f <i>address_family</i>] </pre>														
DESCRIPTION	<p>netstat displays the contents of certain network-related data structures in various formats, depending on the options you select.</p> <p>The first form of the command displays a list of active sockets for each protocol. The second form selects one from among various other network data structures. The third form shows the state of the interfaces. The fourth form displays the routing table, the fifth form displays the multicast routing table, and the sixth form displays the state of DHCP on one or all interfaces.</p> <p>With no arguments, netstat prints connected sockets for PF_INET, PF_INET6, and PF_UNIX, unless modified otherwise by the -f option.</p>														
OPTIONS	<table border="0"> <tr> <td style="vertical-align: top; padding-right: 10px;">-a</td> <td>Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, sockets used by server processes are not shown. Only interface, host, network, and default routes are shown. Also, only the status of physical interfaces are shown.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">-f <i>address_family</i></td> <td> Limit all displays to those of the specified <i>address_family</i>. The value of <i>address_family</i> can be one of the following: <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">inet</td> <td>For the AF_INET address family showing IPv4 information.</td> </tr> <tr> <td style="padding-right: 10px;">inet6</td> <td>For the AF_INET6 address family showing IPv6 information.</td> </tr> <tr> <td style="padding-right: 10px;">unix</td> <td>For the AF_UNIX address family.</td> </tr> </table> </td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">-g</td> <td>Show the multicast group memberships for all interfaces.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">-i</td> <td>Show the state of the interfaces that are used for IP traffic. Normally this shows status and statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See <code>ifconfig(1M)</code>.</td> </tr> </table>	-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, sockets used by server processes are not shown. Only interface, host, network, and default routes are shown. Also, only the status of physical interfaces are shown.	-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following: <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">inet</td> <td>For the AF_INET address family showing IPv4 information.</td> </tr> <tr> <td style="padding-right: 10px;">inet6</td> <td>For the AF_INET6 address family showing IPv6 information.</td> </tr> <tr> <td style="padding-right: 10px;">unix</td> <td>For the AF_UNIX address family.</td> </tr> </table>	inet	For the AF_INET address family showing IPv4 information.	inet6	For the AF_INET6 address family showing IPv6 information.	unix	For the AF_UNIX address family.	-g	Show the multicast group memberships for all interfaces.	-i	Show the state of the interfaces that are used for IP traffic. Normally this shows status and statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See <code>ifconfig(1M)</code> .
-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, sockets used by server processes are not shown. Only interface, host, network, and default routes are shown. Also, only the status of physical interfaces are shown.														
-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following: <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">inet</td> <td>For the AF_INET address family showing IPv4 information.</td> </tr> <tr> <td style="padding-right: 10px;">inet6</td> <td>For the AF_INET6 address family showing IPv6 information.</td> </tr> <tr> <td style="padding-right: 10px;">unix</td> <td>For the AF_UNIX address family.</td> </tr> </table>	inet	For the AF_INET address family showing IPv4 information.	inet6	For the AF_INET6 address family showing IPv6 information.	unix	For the AF_UNIX address family.								
inet	For the AF_INET address family showing IPv4 information.														
inet6	For the AF_INET6 address family showing IPv6 information.														
unix	For the AF_UNIX address family.														
-g	Show the multicast group memberships for all interfaces.														
-i	Show the state of the interfaces that are used for IP traffic. Normally this shows status and statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See <code>ifconfig(1M)</code> .														

netstat(1M)

	-m	Show the STREAMS statistics.
	-n	Show network addresses as numbers. <code>netstat</code> normally displays addresses as symbols. This option may be used with any of the display formats.
	-p	Show the net to media tables.
	-r	Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the <code>-a</code> option, all routes will be printed, including cache.
	-s	Show per-protocol statistics. When used with the <code>-M</code> option, show multicast routing statistics instead. When used with the <code>-a</code> option, per-interface statistics will be displayed, when available, in addition to statistics global to the system.
	-v	Verbose. Show additional information for the sockets and the routing table.
	-I <i>interface</i>	Show the state of a particular interface. <i>interface</i> can be any valid interface such as <code>hme0</code> or <code>le0</code> . Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the <code>-a</code> option, information for the logical interfaces is also reported.
	-M	Show the multicast routing tables. When used with the <code>-s</code> option, show multicast routing statistics instead.
	-P <i>protocol</i>	Limit display of statistics or state of all sockets to those applicable to <i>protocol</i> . The protocol can be one of <code>ip</code> , <code>ipv6</code> , <code>icmp</code> , <code>icmpv6</code> , <code>igmp</code> , <code>udp</code> , <code>tcp</code> , <code>rawip</code> . The command accepts protocol options only as all lowercase.
	-D	Show the status of DHCP configured interfaces.
OPERANDS	<i>interval</i>	If <i>interval</i> is specified, <code>netstat</code> displays interface information over the last <i>interval</i> seconds, repeating forever.
Active Sockets (First Form)		The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol. The symbolic format normally used to display socket addresses is either <code>hostname.port</code> when the name of the host is specified, or <code>network.port</code> if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the *hosts* or *networks* database.

If the network or hostname for an address is not known, or if the `-n` option is specified, the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as "*". For more information regarding the Internet naming conventions, refer to `inet(7P)` and `inet6(7P)`.

TCP Sockets

The possible state values for TCP sockets are as follows:

BOUND	Bound, ready to connect or listen.
CLOSED	Closed. The socket is not being used.
CLOSING	Closed, then remote shutdown; awaiting acknowledgment.
CLOSE_WAIT	Remote shutdown; waiting for the socket to close.
ESTABLISHED	Connection has been established.
FIN_WAIT_1	Socket closed; shutting down connection.
FIN_WAIT_2	Socket closed; waiting for shutdown from remote.
IDLE	Idle, opened but not bound.
LAST_ACK	Remote shutdown, then closed; awaiting acknowledgment.
LISTEN	Listening for incoming connections.
SYN_RECEIVED	Initial synchronization of the connection under way.
SYN_SENT	Actively trying to establish connection.
TIME_WAIT	Wait after close for remote shutdown retransmission.

Network Data Structures (Second Form)

The form of the display depends upon which of the `-g`, `-m`, `-p`, or `-s` options you select.

<code>-g</code>	Displays the list of multicast group membership.
<code>-m</code>	Displays the memory usage, for example, STREAMS mblks.
<code>-p</code>	Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See <code>arp(1M)</code> . For IPv6, the neighbor cache is displayed.
<code>-s</code>	Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for `ipForwarding` are:

<code>forwarding (1)</code>	Acting as a gateway.
<code>not-forwarding (2)</code>	Not acting as a gateway.

netstat(1M)

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the `-a` option is specified with the `-s` option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

If you specify more than one of these options, `netstat` displays the information for each one of them.

**Interface Status
(Third Form)**

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the `-I` option, it displays information for only the specified interface.

The list consists of the interface name, `mtu` (maximum transmission unit, or maximum packet size)(see `ifconfig(1M)`), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the `Net/Dest` field is the name or address on the other side of the link.

If the `-a` option is specified with either the `-i` option or the `-I` option, then the output includes additional information about the physical interface(s), input packets, input packets and output packets for each logical interface, for example the local IP address, associated with the physical interface(s).

If the `-n` option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continuously displayed in *interval* seconds until interrupted by the user.

The input interface is specified using the `-I` option. In this case, the list only displays traffic information in columns; the specified interface is first, the total count is second. This column list has the format of:

input	le0	output	input	(Total)	output				
packets	errs	packets	errs	packets	errs	colls			
227681	0	659471	1	502	261331	0	99597	1	502
10	0	0	0	0	10	0	0	0	0
8	0	0	0	0	8	0	0	0	0
10	0	2	0	0	10	0	2	0	0

If the input interface is not specified, the first interface of address family `inet` or `inet6` will be displayed.

**Routing Table
(Fourth Form)**

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route (U if "up"), whether the route is to a gateway (G), and whether the route was created dynamically by a redirect (D). If the

-a option is specified, there will be routing entries with flags for combined routing and address resolution entries (A), broadcast addresses (B), and the local addresses for the host (L).

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The use column displays the number of packets sent using a combined routing and address resolution (A) or a broadcast (B) route. For a local (L) route, this count is the number of packets received, and for all other routes it is the number of times the routing entry has been used to create a new combined route and address resolution entry.

The *interface* entry indicates the network interface utilized for the route.

Multicast Routing Tables (Fifth Form)

The multicast routing table consists of the virtual interface table and the actual routing table.

DHCP Interface Information (Sixth Form)

The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in *RFC 2131*.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

BOOTP The interface has a lease obtained through BOOTP.

BUSY The interface is busy with a DHCP transaction.

PRIMARY The interface is the primary interface. See `dhcpiinfo(1)`.

FAILED The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized at zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

FILES

`/etc/default/inet_type` DEFAULT_IP setting

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

netstat(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO dhcpinfo(1), arp(1M), crash(1M), dhcpagent(1M), ifconfig(1M), iostat(1M), mibiisa(1M), savecore(1M), vmstat(1M), hosts(4), inet_type(4), networks(4), protocols(4), services(4), attributes(5), inet(7P), inet6(7P)

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

NOTES When printing interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the crash(1M) utility on the savecore(1M) output.

NAME	newfs – construct a new UFS file system
SYNOPSIS	newfs [-Nv] [<i>mkfs-options</i>] <i>raw-device</i>
DESCRIPTION	<p><i>newfs</i> is a "friendly" front-end to the <i>mkfs</i>(1M) program for making UFS file systems on disk partitions. <i>newfs</i> calculates the appropriate parameters to use and calls <i>mkfs</i>.</p> <p>If run interactively (that is, standard input is a tty), <i>newfs</i> will prompt for confirmation before making the file system.</p> <p>If the -N option is not specified and the inodes of the device are not randomized, <i>newfs</i> will call <i>fsirand</i>(1M).</p> <p>You must be super-user to use this command, except when creating a UFS file system on a <i>diskette</i> (see EXAMPLES).</p>
OPTIONS	<p>The following options are supported:</p> <p>-N Print out the file system parameters that would be used in creating the file system without actually creating the file system. <i>fsirand</i>(1M) is not called here.</p> <p>-v Verbose. <i>newfs</i> prints out its actions, including the parameters passed to <i>mkfs</i>.</p> <p><i>mkfs-options</i> Options that override the default parameters are:</p> <p style="padding-left: 20px;">-a <i>apc</i> The number of alternate blocks per cylinder (SCSI devices only) to reserve for bad block replacement. The default is 0.</p> <p style="padding-left: 20px;">-b <i>bsize</i> The logical block size of the file system in bytes (either 4096 or 8192). The default is 8192. The sun4u architecture does not support the 4096 block size.</p> <p style="padding-left: 20px;">-c <i>cgsize</i> The number of cylinders per cylinder group (ranging from 16 to 256). The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte, and then multiplying the result by 32. The default value will always be between 16 and 256. <i>mkfs</i> may override this value. See <i>mkfs_ufs</i>(1M) for details.</p> <p style="padding-left: 20px;">-d <i>gap</i> Rotational delay. The expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. It is used to decide how much rotational spacing to place between successive blocks in a file. This parameter can be</p>

newfs(1M)

- subsequently changed using the `tunefs(1M)` command. The default is disk-type dependent.
- `-f fragsize` The smallest amount of disk space in bytes to allocate to a file. The values must be a power of two selected from the range 512 to the logical block size. If logical block size is 4096, legal values are 512, 1024, 2048 and 4096; if logical block size is 8192, 8192 is also a legal value. The default is 1024.
- `-i nbpi` The number of bytes per inode. This specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the fixed number of inodes to create. It should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used; to create more inodes a smaller number should be given. The default for *nbpi* is as follows:
- | <i>Disk size</i> | <i>Density</i> |
|------------------|----------------|
| -1GB | 2048 |
| -2GB | 4096 |
| -3GB | 6144 |
| 3GB- | 8192 |
- `-m free` The minimum percentage of free space to maintain in the file system (between 1% and 99%, inclusively). This space is off-limits to normal users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system. This parameter can be subsequently changed using the `tunefs(1M)` command.
- The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.
- `-n nrpos` The number of different rotational positions in which to divide a cylinder group. The default is 8.
- `-o opt` (*space* or *time*). The file system can either be instructed to try to minimize the time spent

allocating blocks, or to try to minimize the space fragmentation on the disk. The default is `time`.

- `-r rpm` The speed of the disk in revolutions per minute. The default is 3600.
- `-s size` The size of the file system in sectors. The default is to use the entire partition.
- `-t ntrack` The number of tracks per cylinder on the disk. The default is taken from the disk label.
- `-C maxcontig` The maximum number of blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay. The default is determined from the disk drives maximum transfer rate. The maximum `maxcontig` that UFS supports is 1048576. This parameter can be subsequently changed using the `tunefs(1M)` command.

This parameter also controls clustering. Regardless of the value of `gap`, clustering is enabled only when `maxcontig` is greater than 1. Clustering allows higher I/O rates for sequential I/O and is described in `tunefs(1M)`.

OPERANDS The following operands are supported:

raw-device The name of a raw special device residing in `/dev/rdisk` (for example, `/dev/rdisk/c0t0d0s6`) on which to create the file system.

USAGE See `largefile(5)` for the description of the behavior of `newfs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Verbosely displaying the parameters for the raw special device.

The following example verbosely displays the parameters for the raw special device, `c0t0d0s6`, but does not actually create a new file system:

```
example# newfs -Nv /dev/rdisk/c0t0d0s6
mkfs -F ufs -o N /dev/rdisk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
2048 t 0 -1 8 /dev/rdisk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

newfs(1M)

EXAMPLE 1 Verbosely displaying the parameters for the raw special device. (Continued)

EXAMPLE 2 Creating a UFS file system.

The following example uses the command to create a UFS file system on a diskette that is managed by Volume Manager.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, . . .
```

EXIT STATUS The following exit values are returned:

0 The operation was successful.
1, 10 Usage error or internal error. A message is output to `STDERR` explaining the error.

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fsck(1M)`, `fsck_ufs(1M)`, `fsirand(1M)`, `mkfs(1M)`, `mkfs_ufs(1M)`, `tunefs(1M)`, `fs_ufs(4)`, `attributes(5)`, `largefile(5)`

DIAGNOSTICS `newfs`: No such file or directory
The device specified does not exist, or a disk partition was not specified.
`special`: cannot open
You must be super-user to use this command.

NAME	newkey – create a new Diffie-Hellman key pair in the publickey database				
SYNOPSIS	<pre>newkey -h <i>hostname</i> [-s nisplus nis files] newkey -u <i>username</i> [-s nisplus nis files]</pre>				
DESCRIPTION	<p>newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.</p> <p>newkey prompts for a password for the given <i>username</i> or <i>hostname</i> and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the <code>/etc/publickey</code> file, the NIS <code>publickey</code> map, or the NIS+ <code>cred.org_dir</code> table.</p> <p>newkey consults the <code>publickey</code> entry in the name service switch configuration file (see <code>nsswitch.conf(4)</code>) to determine which naming service is used to store the secure RPC keys. If the <code>publickey</code> entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the <code>-s</code> option.</p> <p>In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain. In the case of NIS+, newkey should be run by the superuser on a machine which has permission to update the <code>cred.org_dir</code> table of the new user/host domain.</p> <p>In the case of NIS+, <code>nisaddcred(1M)</code> should be used to add new keys. newkey cannot be used to create keys other than 192-bit Diffie-Hellman.</p>				
OPTIONS	<pre>-h <i>hostname</i> Create a new public/secret key pair for the privileged user at the given hostname. Prompts for a password for the given hostname. -u <i>username</i> Create a new public/secret key pair for the given <i>username</i>. Prompts for a password for the given <i>username</i>. -s nisplus -s nis -s files Update the database in the specified source: nisplus (for NIS+), nis (for NIS), or files. Other sources may be available in the future.</pre>

nfsd(1M)

NAME	nfsd – NFS daemon
SYNOPSIS	<code>/usr/lib/nfs/nfsd [-a] [-c #_conn] [-l listen_backlog] [-p protocol] [-t device] [nservers]</code>
DESCRIPTION	<p>nfsd is the daemon that handles client file system requests. Only the super-user can run this daemon.</p> <p>The nfsd daemon is automatically invoked in run level 3 with the -a option.</p> <p>By default nfsd will start over the tcp and udp transports.</p> <p>A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Start a NFS daemon over all available connectionless and connection-oriented transports, including udp and tcp.-c #_conn This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited.-l Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries.-p protocol Start a NFS daemon over the specified protocol.-t device Start a NFS daemon for the transport specified by the given device.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none">nservers This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to nservers threads created as needed in the kernel. nservers should be based on the load expected on this server. 16 is the usual number of nservers. If nservers is not specified, the maximum number of concurrent NFS requests will default to 1.
USAGE	<p>If the NFS_PORTMON variable is set, then clients are required to use privileged ports (ports < IPPORT_RESERVED) in order to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfssrv" module. To set the variable, edit the /etc/system file and add this entry:</p> <pre>set nfssrv:nfs_portmon = 1</pre>
EXIT STATUS	<ul style="list-style-type: none">0 Daemon started successfully.1 Daemon failed to start.

FILES	.nfsXXX	client machine pointer to an open-but-unlinked file
	/etc/init.d/nfs.server	shell script for starting nfsd
	/etc/system	system configuration information file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

System Administration Guide, Volume 3

- NOTES**
1. The NFS service uses kernel threads to process all of the NFS requests. Currently, system utilization associated with these threads is not charged to the `nfsd` process. Therefore, `ps(1)` can report 0 cpu time associated with the NFS daemon, even though NFS processing is taking place on the server.
 2. Manually starting and restarting `nfsd` is not recommended. If it is necessary to do so, use the NFS server start/stop script (`/etc/init.d/nfs.server`). See *System Administration Guide, Volume 3* for more information.

nfslogd(1M)

NAME	nfslogd – nfs logging daemon
SYNOPSIS	<code>/usr/lib/nfs/nfslogd</code>
DESCRIPTION	<p>The <code>nfslogd</code> daemon provides operational logging to the Solaris NFS server. It is the <code>nfslogd</code> daemon's job to generate the activity log by analyzing the RPC operations processed by the the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the <code>share_nfs(1M)</code> command.</p> <p>Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as <code>mkdir</code>, <code>rmdir</code>, and <code>remove</code>. The extended format is not compatible with the Washington University FTPd daemon format. See <code>nfslog.conf(4)</code> for details.</p> <p>The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the <code>/etc/nfs/nfslog.conf</code> file. Refer to <code>nfslog.conf(4)</code> for more information. The second phase involves the <code>nfslogd</code> user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The <code>nfslogd</code> daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the <code>IDLE_TIME</code> parameter in <code>/etc/default/nfslogd</code>. The work buffers are intended for internal consumption of the <code>nfslogd</code> daemon.</p> <p>NFS operations use file handles as arguments instead of path names. For this reason the <code>nfslogd</code> daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.</p> <p>Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the <code>htable</code> parameter in the <code>/etc/nfs/nfslog.conf</code> file. This database is intended for the internal use of the <code>nfslogd</code> daemon.</p> <p>In order to keep the size of the file handle mapping database manageable, <code>nfslogd</code> prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The <code>PRUNE_TIMEOUT</code> configurable parameter in <code>/etc/default/nfslogd</code> specifies the interval length between</p>

successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the `PRUNE_TIMEOUT` as high as `INT_MAX`.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the `PRUNE_TIMEOUT` and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the `nfslogd` daemon. These parameters are found in `/etc/default/nfslogd` and are described below:

<code>UMASK</code>	Sets the file mode for the log files, work buffer files and file handle mapping database.
<code>MIN_PROCESSING_SIZE</code>	Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of <code>MIN_PROCESSING_SIZE</code> must be between 1 and <code>ulimit</code> .
<code>IDLE_TIME</code>	Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. <code>IDLE_TIME</code> also determines how often the configuration file will be reread. The value of <code>IDLE_TIME</code> must be between 1 and <code>INT_MAX</code> .
<code>MAX_LOGS_PRESERVE</code>	The <code>nfslogd</code> periodically cycles its logs. <code>MAX_LOGS_PRESERVE</code> specifies the maximum number of log files to save. When <code>MAX_LOGS_PRESERVE</code> is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with <code>filename.0</code> . The oldest file will have the highest numbered extension up to the value configured for <code>MAX_LOGS_PRESERVE</code> . The value of <code>MAX_LOGS_PRESERVE</code> must be between 1 and <code>INT_MAX</code> .
<code>CYCLE_FREQUENCY</code>	Specifies how often, in hours, the log files are cycled. <code>CYCLE_FREQUENCY</code> is used to insure that the log files do not get too large.

nfslogd(1M)

MAPPING_UPDATE_INTERVAL The value of `CYCLE_FREQUENCY` must be between 1 and `INT_MAX`.
Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the `atime` of a record each time that record is accessed, it is only updated if it has aged based on this parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and `INT_MAX`.

PRUNE_TIMEOUT Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than `PRUNE_TIMEOUT` then the record can be pruned from the database. The default value for `PRUNE_TIMEOUT` is 168 hours (7 days). The value of `PRUNE_TIMEOUT` must be between 1 and `INT_MAX`.

EXIT STATUS The following exit values are returned:

- 0 Daemon started successfully.
- 1 Daemon failed to start.

NAME	nfsstat – NFS statistics						
SYNOPSIS	nfsstat [-cnrsmza]						
DESCRIPTION	<p>nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is</p> <pre>nfsstat -csnra</pre> <p>That is, display everything, but reinitialize nothing.</p>						
OPTIONS	<p>-a Display NFS_ACL information.</p> <p>-c Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only.</p> <p>-m Display statistics for each NFS mounted file system. This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. Note that the dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.</p> <p> If you specify the -m option, this is the only option nfsstat uses. Any options specified in addition to -m are checked for validity, then ignored.</p> <p>-n Display NFS information. NFS information for both the client and server side will be printed. Can be combined with the -c and -s options to print client or server NFS information only.</p> <p>-r Display RPC information.</p> <p>-s Display server information.</p> <p>-z Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.</p>						
DISPLAYS	<p>The server RPC display includes the following fields:</p> <table border="0"> <tr> <td style="padding-right: 20px;">calls</td> <td>The total number of RPC calls received.</td> </tr> <tr> <td>badcalls</td> <td>The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).</td> </tr> <tr> <td>nullrecv</td> <td>The number of times an RPC call was not available when it was thought to be received.</td> </tr> </table>	calls	The total number of RPC calls received.	badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).	nullrecv	The number of times an RPC call was not available when it was thought to be received.
calls	The total number of RPC calls received.						
badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).						
nullrecv	The number of times an RPC call was not available when it was thought to be received.						

nfsstat(1M)

badlen	The number of RPC calls with a length shorter than a minimum-sized RPC call.
xdr call	The number of RPC calls whose header could not be XDR decoded.
dupchecks	The number of RPC calls that looked up in the duplicate request cache.
dupreqs	The number of RPC calls that were found to be duplicates.

The server NFS display shows the number of NFS calls received (`calls`) and rejected (`badcalls`), and the counts and percentages for the various calls that were made.

The server NFS_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

calls	The total number of RPC calls made.
badcalls	The total number of calls rejected by the RPC layer.
badxids	The number of times a reply from a server was received which did not correspond to any outstanding call.
timeouts	The number of times a call timed out while waiting for a reply from the server.
newcreds	The number of times authentication information had to be refreshed.
badverfs	The number of times the call failed due to a bad verifier in the response.
timers	The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.
cantconn	The number of times the call failed due to a failure to make a connection to the server.
nomem	The number of times the call failed due to a failure to allocate memory.
interrupts	The number of times the call was interrupted by a signal before completing.
retrans	The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.
cantsend	The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the CLIENT handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See `mount_nfs(1M)`.

The following mount flags are set by mount options:

<code>sec</code>	<code>sec</code> has one of the following values:
	<code>none</code> No authentication.
	<code>sys</code> UNIX-style authentication (UID, GID).
	<code>short</code> Short hand UNIX style authentication.
	<code>dh</code> <code>des</code> —style authentication (encrypted timestamps).
	<code>krb4</code> <code>kerberos v4</code> —style authentication.
	<code>krb5</code> <code>kerberos v5</code> —style authentication.
	<code>krb5i</code> <code>kerberos v5</code> —style authentication with integrity.
<code>hard</code>	Hard mount.
<code>soft</code>	Soft mount.
<code>intr</code>	Interrupts allowed on hard mount.
<code>nointr</code>	No interrupts allowed on hard mount.
<code>noac</code>	Client is not caching attributes.
<code>rsize</code>	Read buffer size in bytes.
<code>wsize</code>	Write buffer size in bytes.
<code>retrans</code>	NFS retransmissions.
<code>timeo</code>	Initial NFS timeout, in tenths of a second.
<code>nocto</code>	No close-to-open consistency.
<code>llock</code>	Local locking being used (no lock manager).
<code>grpuid</code>	System V group id inheritance.
<code>rpctimesync</code>	RPC time sync.

The following mount flags are internal to the system:

<code>printed</code>	"Not responding" message printed.
----------------------	-----------------------------------

nfsstat(1M)

<code>down</code>	Server is down.
<code>dynamic</code>	Dynamic transfer size adjustment.
<code>link</code>	Server supports links.
<code>symlink</code>	Server supports symbolic links.
<code>readdir</code>	Use <code>readdir</code> instead of <code>readdirplus</code> .
<code>acl</code>	Server supports NFS_ACL.

The following flags relate to additional mount information:

<code>vers</code>	NFS version.
<code>proto</code>	Protocol.

The `-m` option also provides attribute cache timeout values. The following fields in `-m` output provide timeout values for attribute cache:

<code>acregmin</code>	Minimum seconds to hold cached file attributes.
<code>acregmax</code>	Maximum seconds to hold cached file attributes.
<code>acdirmin</code>	Minimum seconds to hold cached directory attributes.
<code>acdirmax</code>	Maximum seconds to hold cached directory attributes.

The following fields in `-m` output provide failover information:

<code>noresponse</code>	How many times servers have failed to respond.
<code>failover</code>	How many times a new server has been selected.
<code>remap</code>	How many times files have been re-evaluated to the new server.
<code>currserver</code>	Which server is currently providing NFS service. See the <i>System Administration Guide, Volume 3</i> for additional details.

The fields in `-m` output shown below provide information on dynamic retransmissions. Note that these items are displayed only where dynamic retransmission is in use.

<code>srtt</code>	The value for the smoothed round-trip time, in milliseconds.
<code>dev</code>	Estimated deviation, in milliseconds.
<code>cur</code>	Current backed-off retransmission value, in milliseconds.

EXIT STATUS The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

nisaddcred(1M)

NAME | nisaddcred – create NIS+ credentials

SYNOPSIS | **nisaddcred** [-p *principal*] [-P *nis_principal*] [-l *login_password*] *auth_type*
| [*domain_name*]

| **nisaddcred** -r [*nis_principal*] [*domain_name*]

DESCRIPTION | The `nisaddcred` command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name.

| When the `nisaddcred` command is run, these credentials get created and stored in a table named `cred.org_dir` in the default NIS+ domain. If *domain_name* is specified, the entries are stored in the `cred.org_dir` of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords.

| It is simpler to add credentials using `nisclient(1M)`, because it obtains the required information itself. `nispopulate(1M)` is used for “bulk” updates and can also be used to add credentials for entries in the `hosts` and the `passwd` NIS+ tables.

| NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the “Principal Names” subsection of the `nis+(1)` manual page. See `nischmod(1)`, `nischown(1)`, `nis_objects(3NSL)`, and `nis_groups(3NSL)`. Various other services can also implement access control based on these principal names.

| The `cred.org_dir` table is organized as follows:

cname	auth_type	auth_name	public_data	private_data
user1.foo.com.	LOCAL	2990	10,102,44	
user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2
user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32

| The `cname` column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot (‘.’) followed by the fully qualified “home” domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the `domainname(1M)` command executed on that host.

| There are two basic types of *auth_type* entries in the `cred.org_dir` table, those with authentication type `LOCAL`, and those with authentication type `DES`, *auth_type*, specified on the command line in upper or lower case, should be either *local* or *des*.

However, the `cred.org_dir` table may also be used to hold data for other values of *auth_type*. Currently, this is limited to the mechanisms listed on the `nisauthconf(1M)` man page, for which the `nisaddcred auth_type` argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the *auth_type* is `des`, and other authentication mechanisms are configured with `nisauthconf(1M)`, then credential entries are added or updated for each mechanism configured. To only add or update 1992-bit Diffie Hellman credentials, that is, those with the *auth_type* of DES, use `dh192-0` on the command line. If there are no authentication mechanisms configured, using `des` on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the `cred.org_dir` table. This correspondence is required when associating requests made using the `AUTH_SYS` RPC authentication flavor (see `rpc_clnt_auth(3NSL)`) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the `cred.org_dir` table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The *auth_name* associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the `cred.org_dir` table. This may differ from that in the principal's home domain. The public information stored in *public_data* for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one `cred.org_dir` table.

The DES *auth_type* is used for Secure RPC authentication (see `secure_rpc(3NSL)`).
