The authentication name associated with the DES *auth_type* is a Secure RPC *netname*. A Secure RPC netname has the form `unix.id@domain.com`, where *domain* must be the same as the domain of the principal. For principals that are users the *id* must be the UID of the principal in the principal's home domain. For principals that are hosts, the *id* is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.

nisaddcred(1M)

User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the `cred.org_dir` table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name *nobody* for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the `cred` table.

If credentials are being added for the caller itself, `nisaddcred` automatically performs a `keylogin` for the caller.

You can list the `cred` entries for a particular principal with `nismatch(1)`.

OPTIONS

The following options are supported:

- `-p principal` The name *principal* specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form `unix.id@domain.com`, as described earlier. If the `-p` option is not specified, the *auth_name* field is constructed from the effective UID of the current process and the name of the local domain.
- `-P nis_principal` Use the NIS+ principal name *nis_principal*. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine's default domain.
- Whenever the `-P` option is not specified, `nisaddcred` constructs a principal name for the entry as follows. When it is not creating an entry of type LOCAL, `nisaddcred` calls `nis_local_principal`, which looks for an existing LOCAL entry for the effective UID of the current process in the `cred.org_dir` table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, `nisaddcred` constructs a default NIS+ principal name by taking the login name of the effective UID for its own process, and appending to it a dot ('.') followed by the local machine's default domain. If the caller is a superuser, the machine name is used instead of the login name.

-l <i>login_password</i>	Use the <i>login_password</i> specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration scripts only. Prompting guarantees not only that no one can see your password on the command line using <code>ps(1)</code> but it also checks to make sure you have not made any mistakes. NOTE: <i>login_password</i> does not really HAVE to be the user's password but if it is, it simplifies logging in.
-r [<i>nis_principal</i>]	Remove all credentials associated with the principal <i>nis_principal</i> from the <code>cred.org_dir</code> table. This option can be used when removing a client or user from the system. If <i>nis_principal</i> is not specified the default is to remove credentials for the current <i>user</i> . If <i>domain_name</i> is not specified, the operation is executed in the default NIS+ domain.

EXAMPLES**EXAMPLE 1** How to add the LOCAL and DES credentials.

The following examples illustrate how to add the LOCAL and DES credentials for some user, *user1*, with a UID of 2990, who is an NIS+ user principal in the `some.domain.com`. NIS+ domain:

```
example% nisaddcred -p 2990 \  
-P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless *domain_name* is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then *domain_name* should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See `nisauthconf(1M)`.

Note that the secure RPC netname does not end with a dot ('.') while the NIS+ principal name (specified with the `-P` option) does. This command should be executed from a machine in the same domain as is the user.

The following example shows how to add a machine's DES credentials in the same domain:

nisaddcred(1M)

EXAMPLE 1 How to add the LOCAL and DES credentials. (Continued)

```
example% nisaddcred -p unix.foo@some.domain.com \  
-P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```
example% nisaddcred -p unix.host1@sub.some.domain.com \  
-P newhost.sub.some.domain.com. des sub.some.domain.com.
```

This format is particularly useful if you are running this command from a server which is in a higher domain than sub.some.domain.com. Without the last option for domain name, `nisaddcred` would fail because it would attempt to use the default domain of some.domain.com.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with `nisauthconf(1M)`. See `nisauthconf(1M)` for a list of the valid values of `auth_type`:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user.1.some.domain.com dh640-0
```

Note, the password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run `chkey(1)` using the `-p` option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user1.some.domain.com dh192-0
```

EXIT STATUS The following exit values are returned:

0	Successful operation.
1	Operation failed.

NOTES | The cred.org_dir NIS+ table replaces the maps *publickey.byname* and *netid.byname*
used in NIS (YP).

If a *nisdomain* is specified, *nisaddent* operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (-y).

To accommodate other credential entries used by other authentication mechanisms stored in the *cred.org_dir* table, the *publickey* dump output has been modified to include a special algorithm *type* field. This format is incompatible with older versions of *nisaddent*. To produce dumps that can be read by older versions of *nisaddent*, or to load dumps created by such older versions, use the -o option.

OPTIONS

The following options are supported:

- a Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.
- A All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.
- d Dump the NIS+ table to the standard output in the appropriate format for the given *type*. For tables of type *key-value*, use *niscat(1)* instead. To dump the *cred* table, dump the *publickey* and the *netid* types.
- D *defaults* This option specifies a different set of defaults to be used during this operation. The *defaults* string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

<i>t</i> <i>tl</i> = <i>time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <i>nischttl(1)</i> command. The default is 12 hours.
<i>owner</i> = <i>ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.
<i>group</i> = <i>groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.

nisaddent(1M)

	<code>access=rights</code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default is - - - -rmdr - - -r - - -
<code>-f file</code>		Specify that <code>file</code> should be used as the source of input (instead of the standard input).
<code>-m</code>		Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the <code>-m</code> option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the <code>-r</code> option.
<code>-M</code>		Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.
<code>-o</code>		Use strictly conforming <code>publickey</code> files. Dumps will not add the <code>algorithm type</code> field used by additional authentication mechanisms that might be configured using <code>nisauthconf(1M)</code> . 192-bit keys that are dumped using this option can be read by previous versions of <code>nisaddent</code> . However, the <code>algorithm</code> field will be lost and assumed to be "0" when read. Use the <code>-o</code> option when reading <code>publickey</code> files from previous versions of <code>nisaddent</code> to avoid warnings about the missing <code>algorithm</code> field.
<code>-p</code>		Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).
<code>-P</code>		Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.
<code>-q</code>		Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables (e.g., <code>hosts</code>), multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for large tables, there

	is a chance that the process will run out of virtual memory and the table will not be dumped.
-r	Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (<code>/etc</code> files, or NIS+ maps). This option has the same effect as the <code>-m</code> option. The use of this option is <i>strongly</i> discouraged due to its adverse impact on performance, unless there are a large number of changes.
-t <i>table</i>	Specify that <i>table</i> should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the <code>domainname</code> if it has been specified.
-v	Verbose.
-y <i>ypdomain</i>	Use the <code>dbm</code> files for the appropriate NIS map, from the NIS domain <i>ypdomain</i> , as the source of input. The files are expected to be on the local machine in the <code>/var/yp/<i>ypdomain</i></code> directory. If the machine is not an NIS server, use <code>ypxfr(1M)</code> to get a copy of the <code>dbm</code> files for the appropriate map.
-Y <i>map</i>	Use the <code>dbm</code> files for <i>map</i> as the source of input.

EXAMPLES**EXAMPLE 1** Using `nisaddent`

This example adds the contents of `/etc/passwd` to the `passwd.org_dir` table:

```
example% cat /etc/passwd | nisaddent passwd
```

The next example adds the shadow information. Note that the table type here is “shadow”, not “passwd”, even though the actual information is stored in the `passwd` table:

```
example% cat /etc/shadow | nisaddent shadow
```

This example replaces the `hosts.org_dir` table with the contents of `/etc/hosts` (in verbose mode):

```
example% nisaddent -rv -f /etc/hosts hosts
```

This example merges the `passwd` map from `myypdomain` with the `passwd.org_dir.nisdomain` table (in verbose mode). The example assumes that the `/var/yp/myypdomain` directory contains the `yppasswd` map.

```
example% nisaddent -mv -y myypdomain passwd nisdomain
```

This example merges the `auto.master` map from `myypdomain` with the `auto_master.org_dir` table:

```
example% nisaddent -m -y myypdomain -Y auto.master \
-t auto_master.org_dir key-value
```

This example dumps the `hosts.org_dir` table:

nisaddent(1M)

EXAMPLE 1 Using nisaddent (Continued)

```
example% nisaddent -d hosts
```

This example dumps the ipnodes.org_dir table:

```
example% nisaddent -d ipnodes
```

ENVIRONMENT VARIABLES

NIS_DEFAULTS This variable contains a default string that will override the NIS+ standard defaults. If the -D switch is used, those values will then override both the NIS_DEFAULTS variable and the standard defaults. To avoid security accidents, the access rights in the NIS_DEFAULTS variable are ignored for the passwd table (but access rights specified with -D are used).

NIS_PATH If this variable is set, and neither the nisdomain nor the table are fully qualified, each directory specified in NIS_PATH will be searched until the table is found (see nisdefaults(1)).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure caused by an error other than parsing.
- 2 A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

NAME	nisauthconf – configure NIS+ security								
SYNOPSIS	nisauthconf [-v] [<i>mechanism</i> , ...]								
DESCRIPTION	<p>nisauthconf controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the AUTH_DES authentication flavor when running security level 2. See rpc.nisd(1M).</p> <p>nisauthconf takes a list of authentication <i>mechanism</i>'s in order of preference. An authentication <i>mechanism</i> may use one or more authentication flavors listed below. If des is the only specified mechanism, then NIS+ only use AUTH_DES with other NIS+ clients and servers. If des is the first mechanism, then other authentication <i>mechanism</i>'s after des will be ignored by NIS+, except for nisaddcred(1M). After changing the mechanism configuration, the keyserver(1M) daemon must be restarted. Note that doing so will remove encryption keys stored by the running keyserver process. This means that a reboot usually is the safest option when the mechanism configuration has been changed.</p> <p>The following mechanisms are available:</p> <table border="1" data-bbox="461 940 1429 1180"> <thead> <tr> <th>Authentication <i>mechanism</i></th> <th>Authentication Flavor</th> </tr> </thead> <tbody> <tr> <td>des</td> <td>AUTH_DES</td> </tr> <tr> <td>dh640-0</td> <td>RPCSEC_GSS using 640-bit Diffie-Hellman keys</td> </tr> <tr> <td>dh1024-0</td> <td>RPCSEC_GSS using 1024-bit Diffie-Hellman keys</td> </tr> </tbody> </table> <p>If no mechanisms are specified, then a list of currently configured mechanisms is printed.</p>	Authentication <i>mechanism</i>	Authentication Flavor	des	AUTH_DES	dh640-0	RPCSEC_GSS using 640-bit Diffie-Hellman keys	dh1024-0	RPCSEC_GSS using 1024-bit Diffie-Hellman keys
Authentication <i>mechanism</i>	Authentication Flavor								
des	AUTH_DES								
dh640-0	RPCSEC_GSS using 640-bit Diffie-Hellman keys								
dh1024-0	RPCSEC_GSS using 1024-bit Diffie-Hellman keys								
OPTIONS	-v Displays a verbose table listing the currently configured authentication mechanisms.								
EXAMPLES	<p>EXAMPLE 1 Configuring a System with only RPCSEC_GSS Authentication Flavor</p> <p>To configure a system to use only the RPCSEC_GSS authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root:</p> <pre>example# /usr/lib/nis/nisauthconf dh640-0</pre> <p>EXAMPLE 2 Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors</p> <p>To configure a system to use both RPCSEC_GSS (with 640-bit Diffie-Hellman keys) and AUTH_DES authentication flavors:</p> <pre>example# /usr/lib/nis/nisauthconf dh640-0 des</pre>								

nisauthconf(1M)

EXAMPLE 2 Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors *(Continued)*

EXAMPLE 3 Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:

```
example# /usr/lib/nis/nisauthconf des dh640-0
```

Note that except for `nisaddcred(1M)`, NIS+ will not use mechanisms that follow 'des.'

EXIT STATUS The following exit values are returned:

0 Successful completion.

1 An error occurred.

FILES `/etc/rpcsec/nisplussec.conf`

NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nis+(1)`, `key serv(1M)`, `nisaddcred(1M)`, `rpc.nisd(1M)`, `attributes(5)`

NOTES A NIS+ client of a server that is configured for either `dh640-0` or `dh1024-0` must run Solaris 7, even if the server is also configured with `des`.

NAME	nisbackup – backup NIS+ directories
SYNOPSIS	<p>nisbackup [-v] <i>backup-dir</i> <i>directory...</i></p> <p>nisbackup [-v] -a <i>backup-dir</i></p>
DESCRIPTION	<p>nisbackup backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while nisbackup is running. The <i>backup-dir</i> is a UNIX directory that must exist prior to running nisbackup. The nisbackup command can be used to backup an individual NIS+ directory object or all (-a) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the <i>backup-dir</i> directory. These subdirectories are named according to the NIS+ directory object they contain. nisbackup operates on individual NIS+ directory objects (for example, <i>org_dir.wiz.com</i>). This allows an administrator to selectively backup specific directories.</p> <p>The <i>rpc.nisd(1M)</i> process must be running on the master server with a stable NIS+ database for nisbackup to complete. nisbackup will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration.</p> <p>The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified.</p> <p>The second synopsis will backup all of the NIS+ directory objects that are served by this master. The -a option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a <i>backup-dir</i> created with the -a option (see <i>nisrestore(1M)</i>).</p>
OPTIONS	<p>-a Creates a backup of all NIS+ directory objects for which this server is a master.</p> <p>-v Verbose option. Additional output will be produced and sent to <i>syslog(3C)</i> upon execution of the command (see <i>syslog.conf(4)</i>).</p>
OPERANDS	<p><i>backup-dir</i> The directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running nisbackup.</p> <p><i>directory</i> The NIS+ directory object(s) being backed up.</p>

nisbackup(1M)

EXAMPLES

EXAMPLE 1 Backup of the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`

To backup the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`:

```
master_server# nisbackup /backup org_dir.foo.com.
```

EXAMPLE 2 Backup of the entire NIS+ domain `foo.com` to a directory named `/backup`

To backup the entire NIS+ domain `foo.com` to a directory named `/backup`:

```
master_server# nisbackup /backup foo.com. \  
org_dir.foo.com. groups_dir.foo.com. \  
ctx_dir.foo.com.
```

EXAMPLE 3 Backup of an entire NIS+ database to a backup directory named `/backup`

To backup an entire NIS+ database to a backup directory named `/backup`:

```
master_server# nisbackup -a /backup
```

EXIT STATUS

0 Successful completion.

1 An error occurred.

FILES

`/backup-dir/backup_list`

This ascii file contains a list of all the objects contained in this *backup-dir* directory.

`/backup-dir/directory-object`

A subdirectory that is created in the *backup-dir* that contains the NIS+ directory-object backup.

`/backup-dir/directory-object/data`

A subdirectory that contains the data files that are part of the NIS+ directory-object backup.

`/backup-dir/directory-object/last.upd`

This data file contains timestamp information about the directory-object.

`/backup-dir/directory-object/data.dict`

A NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO nis+(1), nisdefaults(1), nisrm(1), nisrestore(1M), rpc.nisd(1M), syslog(3C), xfn(3XFN), nisfiles(4), syslog.conf(4), attributes(5)

NOTES The `-a` option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the `-a` option. The backup of replicated objects must be run on the master server for those objects.

Do not use the same *backup-dir* to backup different master servers. Each master server must have its own *backup-dir*.

`nisbackup` will set the `rpc.nisd(1M)` to read only mode, which will disable updates to the NIS+ database. This is necessary to ensure the consistency of the backup. For this reason, `nisbackup` should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as `nisaddent(1M)` should not be run simultaneously with `nisbackup`.

nis_cachemgr(1M)

NAME	nis_cachemgr – NIS+ utility to cache location information about NIS+ servers						
SYNOPSIS	<code>/usr/sbin/nis_cachemgr [-i] [-v]</code>						
DESCRIPTION	<p>The <code>nis_cachemgr</code> daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information needed to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. <code>nis_cachemgr</code> should be running on all the machines that are using NIS+. However, it is not required that the <code>nis_cachemgr</code> program be running in order for NIS+ requests to be serviced.</p> <p>The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped (see <code>mmap(2)</code>) by all the processes. On start up, <code>nis_cachemgr</code> initializes the cache from the cold start file (see <code>nisinit(1M)</code>) and preserves unexpired entries that already exist in the cache file. Thus, the cache survives machine reboots.</p> <p>The <code>nis_cachemgr</code> program is normally started from a system startup script. <code>nisshowcache(1M)</code> can be used to look at the cached objects and active servers.</p> <p>The <code>nisprefadm(1M)</code> command can be used to control which NIS+ servers the <code>nis_cachemgr</code> program will try to select.</p> <p>The <code>nis_cachemgr</code> program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running <code>nis_cachemgr</code>, security credentials for the host should be added to the <code>cred.org_dir</code> table in the host's domain using <code>nisaddcred(1M)</code>. Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see <code>rpc.nisd(1M)</code>). See the WARNINGS section, below. Additionally, a "keylogin -r" should be done on the machine.</p>						
OPTIONS	<p><code>-i</code> Force <code>nis_cachemgr</code> to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots.</p> <p><code>-v</code> This flag sets verbose mode. In this mode, the <code>nis_cachemgr</code> program logs not only errors and warnings, but also additional status messages. The additional messages are logged using <code>syslog(3C)</code> with a priority of <code>LOG_INFO</code>.</p>						
FILES	<table><tr><td><code>/var/nis/NIS_SHARED_DIRCACHE</code></td><td>the shared cache file</td></tr><tr><td><code>/var/nis/NIS_COLD_START</code></td><td>the coldstart file</td></tr><tr><td><code>/etc/init.d/rpc</code></td><td>initialization scripts for NIS+</td></tr></table>	<code>/var/nis/NIS_SHARED_DIRCACHE</code>	the shared cache file	<code>/var/nis/NIS_COLD_START</code>	the coldstart file	<code>/etc/init.d/rpc</code>	initialization scripts for NIS+
<code>/var/nis/NIS_SHARED_DIRCACHE</code>	the shared cache file						
<code>/var/nis/NIS_COLD_START</code>	the coldstart file						
<code>/etc/init.d/rpc</code>	initialization scripts for NIS+						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						

nis_cachemgr(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO keylogin(1), nisaddcred(1M), nisinit(1M), nisprefadm(1M), nisshowcache(1M), rpc.nisd(1M), mmap(2), rpc(3NSL), syslog(3C), nisfiles(4), attributes(5)

DIAGNOSTICS The nis_cachemgr daemon logs error messages and warnings using syslog(3C). Error messages are logged to the DAEMON facility with a priority of LOG_ERR. Warning messages are logged with a priority of LOG_WARNING. Additional status messages can be obtained using the -v option.

nisclient(1M)

NAME	<code>nisclient</code> – initialize NIS+ credentials for NIS+ principals
SYNOPSIS	<pre><code>/usr/lib/nis/nisclient -c [-x] [-o] [-v] [-l <network_password>] [-d <NIS+_domain>] client_name... /usr/lib/nis/nisclient -i [-x] [-v] -h <NIS+_server_host> [-a <NIS+_server_addr>] [-k <key_domain>] [-d <NIS+_domain>] [-s 0 2] /usr/lib/nis/nisclient -u [-x] [-v] /usr/lib/nis/nisclient -r [-x]</code></pre>
DESCRIPTION	<p>The <code>nisclient</code> shell script can be used to:</p> <ul style="list-style-type: none">■ create NIS+ credentials for hosts and users■ initialize NIS+ hosts and users■ restore the network service environment <p>NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service.</p> <p>Use the first synopsis (<code>-c</code>) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The <code>client_name</code> argument accepts any valid host or user name in the NIS+ domain (for example, the <code>client_name</code> must exist in the <code>hosts</code> or <code>passwd</code> table). <code>nisclient</code> verifies each <code>client_name</code> against both the <code>host</code> and <code>passwd</code> tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the <code>host</code> or <code>passwd</code> tables in both the local and remote domains.</p> <p>By default, <code>nisclient</code> will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the <code>-o</code> option. After the credentials have been created, <code>nisclient</code> will print the command that must be executed on the client machine to initialize the host or the user. The <code>-c</code> option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the <code>-l</code> option or the script will prompt you for it. You can change this network password later with <code>nispaswd(1)</code> or <code>chkey(1)</code>.</p> <p><code>nisclient -c</code> is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the <code>passwd</code> and <code>hosts</code> tables. To define credentials for all users and hosts, use <code>nispopulate(1M)</code>.</p> <p>Use the second synopsis (<code>-i</code>) to initialize a NIS+ client machine. <code>-i</code> option can be used to convert machines to use NIS+ or to change the machine's domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using <code>nisclient -c</code> or <code>nispopulate -c</code>. You will need the network password your administrator created. <code>nisclient</code> will prompt you for the network password to decrypt your secret key and then for this machine's root login password to generate a</p>

new set of secret/public keys. If the NIS+ credential was created by your administrator using `nisclient -c`, then you can simply use the initialization command that was printed by the `nisclient` script to initialize this host instead of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the “-i” option with “-S 0”. With these options, the `nisclient -i` option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as `<files>.no_nisplus`. The files that are usually modified during a client initialization are: `/etc/defaultdomain`, `/etc/nsswitch.conf`, `/etc/inet/hosts`, and, if it exists, `/var/nis/NIS_COLD_START`. Note that a file will not be saved if a backup file already exists.

The `-i` option does not set up an NIS+ client to resolve hostnames using DNS. Please refer to the DNS documentation for information on setting up DNS. (See `resolv.conf(4)`).

It is not necessary to initialize either NIS+ root master servers or machines that were installed as NIS+ clients using `suninstall(1M)`.

Use the third synopsis (`-u`) to initialize a NIS+ user. You must be logged in as the user on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your administrator should have already created the NIS+ credential for your username using `nisclient -c` or `nispopulate(1M)`. You will need the network password your administrator used to create the NIS+ credential for your username. `nisclient` will prompt you for this network password to decrypt your secret key and then for your login password to generate a new set of secret/public keys.

Use the fourth synopsis (`-r`) to restore the network service environment to whatever you were using before `nisclient -i` was executed. You must be logged in as super-user on the machine that is to be restored. The restore will only work if the machine was initialized with `nisclient -i` because it uses the backup files created by the `-i` option.

Reboot the machine after initializing a machine or restoring the network service.

OPTIONS

- | | |
|--|--|
| <code>-a <NIS+_server_addr></code> | Specifies the IP address for the NIS+ server. This option is used <i>only</i> with the <code>-i</code> option. |
| <code>-c</code> | Adds DES credentials for NIS+ principals. |
| <code>-d <NIS+_domain></code> | Specifies the NIS+ domain where the credential should be created when used in conjunction with the <code>-c</code> option. It specifies the name for the new NIS+ domain when used in conjunction with the <code>-i</code> option. The default is your current domainname. |

nisclient(1M)

-h <NIS+_server_host>	Specifies the NIS+ server's hostname. This option is used <i>only</i> with the -i option.
-i	Initializes an NIS+ client machine.
-l <network_password>	Specifies the network password for the clients. This option is used <i>only</i> with the -c option. If this option is not specified, the script will prompt you for the network password.
-k <key_domain>	This option specifies the domain where root's credentials are stored. If a domain is not specified, then the system default domain is assumed.
-o	Overwrite existing credential entries. The default is not to overwrite. This is used <i>only</i> with the -c option.
-r	restores the network service environment.
-s 0 2	Specifies the authentication level for the NIS+ client. Level 0 is for unauthenticated clients and level 2 is for authenticated (DES) clients. The default is to set up with level 2 authentication. This is used <i>only</i> with the -i option. <code>nisclient</code> always uses level 2 authentication (DES) for both -c and -u options. There is no need to run <code>nisclient</code> with -u and -c for level 0 authentication. To configure authentication mechanisms other than DES at security level 2, use <code>nisauthconf(1M)</code> before running <code>nisclient</code> .
-u	Initializes an NIS+ user.
-v	Runs the script in verbose mode.
-x	turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.

EXAMPLES

EXAMPLE 1 Adding the DES credential for host *sunws* and user *fred* in the local domain

To add the DES credential for host *sunws* and user *fred* in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

To add the DES credential for host *sunws* and user *fred* in domain *xyz.sun.com.:*

EXAMPLE 1 Adding the DES credential for host *sunws* and user *fred* in the local domain
(Continued)

```
example% /usr/lib/nis/nisclient -c -d xyz.sun.com. sunws fred
```

To initialize host *sunws* as an NIS+ client in domain *xyz.sun.com.* where *nisplus_server* is a server for the domain *xyz.sun.com.:*

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.sun.com.
```

The script will prompt you for the IP address of *nisplus_server* if the server is not found in the */etc/hosts* file. The *-d* option is needed only if your current domain name is different from the new domain name.

To initialize host *sunws* as an unauthenticated NIS+ client in domain *xyz.sun.com.* where *nisplus_server* is a server for the domain *xyz.sun.com.*

```
example# /usr/lib/nis/nisclient -i -S 0 \  
-h nisplus_server -d xyz.sun.com. -a 129.140.44.1
```

To initialize user *fred* as an NIS+ principal, log in as user *fred* on an NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

FILES	<i>/var/nis/NIS_COLD_START</i>	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machines default domain.
	<i>/etc/defaultdomain</i>	the system default domainname
	<i>/etc/nsswitch.conf</i>	configuration file for the name-service switch
	<i>/etc/inet/hosts</i>	local host name database

nisinit(1M)

NAME	<code>nisinit</code> – NIS+ client and server initialization utility
SYNOPSIS	<pre>nisinit -r nisinit -pY D Nparent_domain host... nisinit -c [-k <key_domain>] -H host -B -C coldstart</pre>
DESCRIPTION	<p><code>nisinit</code> initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use <code>nisclient(1M)</code> or <code>nisserver(1M)</code> to accomplish this same task.</p>
OPTIONS	<p><code>-r</code></p> <p>Initialize the machine to be a NIS+ root server. This option creates the file <code>/var/nis/data/root.object</code> and initialize it to contain information about this machine. It uses the <code>sysinfo(2)</code> system call to retrieve the name of the default domain.</p> <p>To initialize the machine as an NIS+ root server, it is advisable to use the “<code>-r</code>” option of <code>nisserver(1M)</code>, instead of using “<code>nisinit -r</code>”.</p> <p><code>-p Y D N parent_domain host . . .</code></p> <p>This option is used on a root server to initialize a <code>/var/nis/data/parent.object</code> to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace “above” the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error <code>NIS_FOREIGNNS</code> indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process.</p> <p>The parameter <i>parent_domain</i> is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain.</p> <p>Y Specifies that the parent directory is a NIS version 2 domain.</p> <p>D Specifies that the parent directory is a DNS domain.</p> <p>N Specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace.</p> <p>Note that in the current implementation, the NIS+ clients do not take advantage of the <code>-p</code> feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used.</p>

-c

Initializes the machine to be a NIS+ client. There are three initialization options available: initialize by coldstart, initialize by hostname, and initialize by broadcast. The most secure mechanism is to initialize from a trusted coldstart file. The second option is to initialize using a hostname that you specify as a trusted host. The third method is to initialize by broadcast and it is the least secure method.

-C coldstart Causes the file *coldstart* to be used as a prototype coldstart file when initializing a NIS+ client. This coldstart file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with `uuencode(1C)`) the coldstart file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with `uudecode`), decrypt, and then use this file with the `nisinit` command to initialize the machine as an NIS+ client. If the coldstart file is from another client in the same domain, the `nisinit` command may be safely skipped and the file copied into the `/var/nis` directory as `/var/nis/NIS_COLD_START`.

-H hostname Specifies that the host *hostname* should be contacted as a trusted NIS+ server. The `nisinit` command will iterate over each transport in the `NETPATH` environment variable and attempt to contact `rpcbind(1M)` on that machine. This hostname *must* be reachable from the client without the name service running. For IP networks this means that there must be an entry in `/etc/hosts` for this host when `nisinit` is invoked.

-B Specifies that the `nisinit` command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

-k <key_domain>

This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the `/var/nis/NIS_COLD_START` file.

RETURN VALUES

`nisinit` returns 0 on success and 1 on failure.

nisinit(1M)

EXAMPLES **EXAMPLE 1** Initialising the machine as an NIS+ client using the host *freddy* as a trusted server

This example initializes the machine as an NIS+ client using the host *freddy* as a trusted server.

```
example# nisinit -cH freddy
```

EXAMPLE 2 Setting up a client using a trusted coldstart file

This example sets up a client using a trusted coldstart file.

```
example# nisinit -cC /tmp/colddata
```

EXAMPLE 3 Setting up a client using an IP broadcast

This example sets up a client using an IP broadcast.

```
example# nisinit -cB
```

EXAMPLE 4 Setting up a root server

This example sets up a root server.

```
example# nisinit -r
```

ENVIRONMENT VARIABLES

NETPATH This environment variable may be set to the transports to try when contacting the NIS+ server (see `netconfig(4)`). The client library will only attempt to contact the server using connection oriented transports.

FILES

`/var/nis/NIS_COLD_START` This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.

`/var/nis/data/root.object` This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify()` interface.

`/var/nis/data/parent.object` This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.

`/etc/hosts` Internet host table.

ATTRIBUTES

nislog(1M)

NAME	nislog – display the contents of the NIS+ transaction log						
SYNOPSIS	<code>/usr/sbin/nislog [-h num -t num] [-v] [directory...]</code>						
DESCRIPTION	<p>nislog displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The <code>/var/nis/trans.log</code> file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed.</p> <p>The <code>nislog</code> command can only be run on an NIS+ server by superuser. It displays the log entries for that server only.</p> <p>If <i>directory</i> is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.</p>						
OPTIONS	<table><tr><td><code>-h num</code></td><td>Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.</td></tr><tr><td><code>-t num</code></td><td>Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.</td></tr><tr><td><code>-v</code></td><td>Verbose mode.</td></tr></table>	<code>-h num</code>	Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.	<code>-t num</code>	Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.	<code>-v</code>	Verbose mode.
<code>-h num</code>	Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.						
<code>-t num</code>	Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.						
<code>-v</code>	Verbose mode.						
FILES	<code>/var/nis/trans.log</code> transaction log

NAME	nisping – send ping to NIS+ servers										
SYNOPSIS	<pre> /usr/lib/nis/nisping [-uf] [-H <i>hostname</i>] [-r <i>directory</i>] /usr/lib/nis/nisping -C [-a] [-H <i>hostname</i>] [<i>directory</i>] </pre>										
DESCRIPTION	<p>In the first SYNOPSIS line, the <code>nisping</code> command sends a “ping” to all replicas of a NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update “seen” by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The <code>-f</code> (force) option will override this feature.</p> <p>Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use <code>nisping</code>.</p> <p>In the second SYNOPSIS line, the <code>nisping -C</code> command sends a checkpoint request to the servers. If no <i>directory</i> is specified, the home domain, as returned by <code>nisdefaults(1)</code>, is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the <code>-a</code> option.</p> <p>On receiving a checkpoint request, the servers would commit all the updates for the given <i>directory</i> from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. <code>nisping</code> should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the <code>crontab(1)</code> file. If the database log files are not checkpointed, their sizes will continue to grow.</p>										
OPTIONS	<table border="0"> <tr> <td style="padding-right: 20px;"><code>-a</code></td> <td>Checkpoint all directories on the server.</td> </tr> <tr> <td><code>-C</code></td> <td>Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.</td> </tr> <tr> <td><code>-H <i>hostname</i></code></td> <td>Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.</td> </tr> <tr> <td><code>-f</code></td> <td>Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.</td> </tr> <tr> <td><code>-r</code></td> <td>This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.</td> </tr> </table> <p>If used without <code>-u</code> option, <code>-r</code> will send a ping request to the servers serving the root domain. When the replicas receive a ping, they will update their root object if needed.</p>	<code>-a</code>	Checkpoint all directories on the server.	<code>-C</code>	Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.	<code>-H <i>hostname</i></code>	Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.	<code>-f</code>	Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.	<code>-r</code>	This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.
<code>-a</code>	Checkpoint all directories on the server.										
<code>-C</code>	Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.										
<code>-H <i>hostname</i></code>	Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.										
<code>-f</code>	Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.										
<code>-r</code>	This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.										

nisping(1M)

The `-r` option can be used with all other options except with the `-C` option; the root object need not be checkpointed.

RETURN VALUES

-u	Display the time of the last update; no servers are sent a ping.
-1	No servers were contacted, or the server specified by the <code>-H</code> switch could not be contacted.
0	Success.
1	Some, but not all, servers were successfully contacted.

EXAMPLES

EXAMPLE 1 Using `nisping`

This example pings all replicas of the default domain:

```
example% nisping
```

Note that this example will not ping the `org_dir` and `groups_dir` subdirectories within this domain.

This example pings the server `example` which is a replica of the `org_dir.foo.com.` directory:

```
example% nisping -H example org_dir.foo.com.
```

This example checkpoints all servers of the `org_dir.bar.com.` directory.

```
example% nisping -C org_dir.bar.com.
```

ENVIRONMENT VARIABLES

<code>NIS_PATH</code>	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.
-----------------------	--

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `crontab(1)`, `nisdefaults(1)`, `nisopaccess(1)`, `nislog(1M)`, `nisfiles(4)`, `attributes(5)`

NOTES If the server specified by the `-H` option does not serve the directory, then no ping is sent.

Per-server and per-directory access restrictions may apply; see `nisopaccess(1)`. `nisping` uses `NIS_CPTIME` and `NIS_PING` (`resync` (`ping`) of replicas), or `NIS_CHECKPOINT` (for checkpoint). Since the `NIS_PING` operation does not return a status, the `nisping` command is typically unable to indicate success or failure for `resyncs`.

NAME	nispopulate – populate the NIS+ tables in a NIS+ domain
SYNOPSIS	<pre> /usr/lib/nis/nispopulate -Y [-x] [-f] [-n] [-u] [-v] [-S 0 2] [-l <network_passwd>] [-d <NIS+_domain>] -h <NIS_server_host> [-a <NIS_server_addr>] -y <NIS_domain> [table] ... /usr/lib/nis/nispopulate -F [-x] [-f] [-u] [-v] [-S 0 2] [-d <NIS+_domain>] [-l <network_passwd>] [-p <directory_path>] [table] ... /usr/lib/nis/nispopulate -C [-x] [-f] [-v] [-d <NIS+_domain>] [-l <network_passwd>] [hosts passwd] </pre>
DESCRIPTION	<p>The nispopulate shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. nispopulate assumes that the tables have been created either through nisserver(1M) or nissetup(1M).</p> <p>The table argument accepts standard names that are used in the administration of Solaris systems and non-standard <i>key-value</i> type tables. See nisaddent(1M) for more information on <i>key-value</i> type tables. If the table argument is not specified, nispopulate will automatically populate each of the standard tables. These standard (default) tables are: auto_master, auto_home, ethers, group, hosts, ipnodes, networks, passwd, protocols, services, rpc, netmasks, bootparams, netgroup, aliases and shadow. Note that the shadow table is only used when populating from files. The non-standard tables that nispopulate accepts are those of <i>key-value</i> type. These tables must first be created manually with the nistbladm(1) command.</p> <p>Use the first synopsis (-Y) to populate NIS+ tables from NIS maps. nispopulate uses ypxfr(1M) to transfer the NIS maps from the NIS servers to the /var/yp/<NIS_domain> directory on the local machine. Then, it uses these files as the input source. Note that <NIS_domain> is case sensitive. Make sure there is enough disk space for that directory.</p> <p>Use the second synopsis (-F) to populate NIS+ tables from local files. nispopulate will use those files that match the table name as input sources in the current working directory or in the specified directory.</p> <p>Note that when populating the hosts, ipnodes, and passwd tables, nispopulate will automatically create the NIS+ credentials for all users and hosts (ipnodes) that are defined in the hosts, ipnodes, and passwd tables, respectively. A network passwd is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the -l option or it will use the default password, "nisplus". nispopulate will not overwrite any existing credential entries in the credential table. Use nisclient(1M) to overwrite the entries in the cred table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the "-S 0" option.</p> <p>The third synopsis (-C) is used to populate NIS+ credential table with level 2 authentication (DES) from the hosts, ipnodes and passwd tables of the specified</p>

nispopulate(1M)

domain. The valid table arguments for this operation are *hosts*, *ipnodes* and *passwd*. If this argument is not specified then it will use *hosts*, *ipnodes* and *passwd* as the input source. If other authentication mechanisms are configured using *nisauthconf(1M)*, the NIS+ credential table will be loaded with credentials for those mechanisms.

If *nispopulate* was earlier used with "-S 0" option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this (-C) option can be used to add credentials.

OPTIONS

- a <*NIS_server_addr*> Specifies the IP address for the NIS server. This option is only used with the -Y option.
- C Populate the NIS+ credential table from *hosts*, *ipnodes*, and *passwd* tables using DES authentication (security level 2). If other authentication mechanisms are configured using *nisauthconf(1M)*, the NIS+ credential table will be populated with credentials for those mechanisms.
- d <*NIS+_domain.*> Specifies the NIS+ domain. The default is the local domain.
- F Populates NIS+ tables from files.
- f Forces the script to populate the NIS+ tables without prompting for confirmation.
- h <*NIS_server_host*> Specifies the NIS server hostname from where the NIS maps are copied from. This is only used with the -Y option. This hostname must be present in the NIS+ *hosts* or *ipnodes* table, or in the */etc/hosts* or */etc/inet/ipnodes* file. If the hostname is not defined, the script will prompt you for its IP address, or you can use the -a option to specify the address manually.
- l <*network_passwd*> Specifies the network password for populating the NIS+ credential table. This is only used when you are populating the *hosts*, *ipnodes*, and *passwd* tables. The default passwd is "nisplus".
- n Does not overwrite local NIS maps in */var/yp/<NISdomain>* directory if they already exist. The default is to overwrite the existing NIS maps in the local */var/yp/<NISdomain>* directory. This is only used with the -Y option.
- p <*directory_path*> Specifies the directory where the files are stored. This is only used with the -F option. The default is the current working directory.

-s 0 2	Specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated (DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run <code>nispopulate</code> with <code>-C</code> for level 0 authentication. Also, if other authentication mechanisms are configured with <code>nisauthconf(1M)</code> , credentials for those mechanisms will also be populated for the NIS+ clients.
-u	Updates the NIS+ tables (ie., adds, deletes, modifies) from either files or NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the <code>-n</code> option for updating NIS+ tables from existing maps in the <code>/var/yp</code> directory.
-v	Runs the script in verbose mode.
-x	Turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
-Y	Populate the NIS+ tables from NIS maps.
-y <NIS_domain>	Specifies the NIS domain to copy the NIS maps from. This is only used with the <code>-Y</code> option. The default domainname is the same as the local domainname.

EXAMPLES **EXAMPLE 1** Using `nispopulate`

To populate all the NIS+ standard tables in the domain `xyz.sun.com`. from NIS maps of the `yp.sun.COM` domain as input source where host `yp_host` is a YP server of `yp.sun.COM`:

```
nis_server# /usr/lib/nis/nispopulate -Y -y yp.sun.COM \
-h yp_host -d xyz.sun.com.
```

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

```
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \
-d xyz.sun.com.
```

To populate the `hosts` table in domain `xyz.sun.com`. from the `hosts` file in the `/var/nis/files` directory and using "somepasswd" as the network password for key encryption:

```
nis_server# /usr/lib/nis/nispopulate -F -p \
/var/nis/files -l somepasswd hosts
```

nispopulate(1M)

EXAMPLE 1 Using nispopulate (Continued)

To populate the passwd table in domain *xyz.sun.com*. from the passwd file in the /var/nis/files directory without automatically creating the NIS+ credentials:

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files \  
-d xys.sun.com. -S 0 passwd
```

To populate the credential table in *domain xyz.sun.com*. for all users defined in the passwd table.

```
nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd
```

To create and populate a non-standard key-value type NIS+ table, "private", from the file /var/nis/files/private: (nispopulate assumes that the private.org_dirkey-value type table has already been created).

```
nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \  
-c private key=S,nogw= value=,nogw= private.org.dir
```

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private
```

ENVIRONMENT VARIABLES

nispopulate normally creates temporary files in the directory /tmp. You may specify another directory by setting the environment variable TMPDIR to your chosen directory. If TMPDIR is not a valid directory, then nispopulate will use /tmp).

FILES

/etc/inet/hosts	local host name database
/etc/inet/ipnodes	local database associating names of nodes with IP addresses
/var/yp	NIS(YP) domain directory
/var/nis	NIS+ domain directory
/tmp

NAME	nisprefadm – NIS+ utility to set server preferences for NIS+ clients
SYNOPSIS	<pre> /usr/bin/nisprefadm -a {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -m {-L -G} [-o opt-string] [-d domain] [-C client] oldserver=newserver... /usr/bin/nisprefadm -r {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -u {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -x {-L -G} [-d domain] [-C client] /usr/bin/nisprefadm -l {-L -G} [-d domain] [-C client] /usr/bin/nisprefadm -F </pre>
DESCRIPTION	<p>nisprefadm defines which servers are to be preferred by NIS+ clients. This information is used by <code>nis_cachemgr(1M)</code> to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in <code>/var/nis</code>. If it doesn't find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn't find it there, it looks for an entry for its subnet.</p> <p>By default, <code>nis_cachemgr</code> puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are <i>closer</i> than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, <code>nisprefadm</code> is used to provide this information.</p> <p>The preferred server information is stored either globally in a NIS+ table (with the <code>-G</code> option) or locally in a file, <code>/var/nis/client_info</code> (with the <code>-L</code> option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The <code>nis_cachemgr</code> process on a client machine reloads the preferred server information periodically, depending on the machine's setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using <code>nischttl(1)</code>. If you want your changes to take effect immediately, use the <code>nisprefadm -F</code> command. When changing local information (<code>-L</code>), <code>nisprefadm</code> automatically forces <code>nis_cachemgr</code> to reload the information.</p> <p>The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, "infinite". This can be changed by using the <code>nisprefadm</code> command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the servers with the lowest weight. If it doesn't get a response, it tries the servers with the</p>

nisprefadm(1M)

next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

OPTIONS

In the `SYNOPSIS`, when several options are surrounded by braces (that is, by '{' and '}') one of the options must be specified.

- a Add the specified servers to the preferred server list.
- C *client* Store the preferred server information with the key, *client*. The *client* can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.
- d *domain* Specify the *domain* to which the command is to apply.
- F Tells `nis_cachemgr(1M)` to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, `nis_cachemgr` automatically refreshes the preferred server information.

 This option must be executed as root.
- l List the current preferred server information.
- L | -G Store the preferred server information locally in the file, `/var/nis/client_info` (the `-L` option), or globally in a NIS+ table `client.info.org-dir.domain` (the `-G` option). If the information is stored locally, then it only applies to the system on

which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the `-C` option).

The `-L` option must be run as `root`.

- `-m` Modify the preferred server list. The server specified by *oldserver* is replaced by *newserver*. This is typically used to change the weight for a server.
- `-o` Specify additional options to control server selection. Currently the only valid option is *pref_type*, which can have a value of either `all` (the default) or `pref_only`. If the value is `all`, then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If `pref_only` is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.
- `-r` Remove the specified servers from the preferred server list.
- `-u` Clear the list of preferred servers and then add the specified servers to the preferred server list.
- `-x` Remove the preferred server information completely.

RETURN VALUES `nisprefadm` returns the following values:

- 0 On success.
- 1 On failure.

EXAMPLES **EXAMPLE 1** Using `nisprefadm`

This command sets the preferred server list for the system on which it is run:

```
example% nisprefadm -L -a srv1 srv2
```

The information is stored in a file, `/var/nis/client_info`, so it will only affect this one system.

The following command has the same effect, but the information is stored in a NIS+ table in the default domain.

```
example% nisprefadm -G -a srv1 srv2
```

As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named *client1*:

```
example% nisprefadm -G -a -C client1 srv1 srv2
```

nisprefadm(1M)

EXAMPLE 1 Using nisprefadm (Continued)

It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, 192.85.18.0:

```
example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `nischttl(1)`, `nis_cachemgr(1M)`, `attributes(5)`

NOTES The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

No local servers, many remote servers

In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn't have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.

Very remote servers

In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the `pref_type=pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.

NAME	nisrestore – restore NIS+ directory backup
SYNOPSIS	<pre> nisrestore [-fv] <i>backup-dir</i> <i>directory...</i> nisrestore [-fv] -a <i>backup-dir</i> nisrestore -t <i>backup-dir</i> </pre>
DESCRIPTION	<p>nisrestore restores an existing backup of a NIS+ directory object that was created using nisbackup(1M). The <i>backup-dir</i> is the UNIX directory that contains the NIS+ backup on the server being restored. The nisrestore command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an "out of band" fast replication for a new replica server being initialized. The rpc.nisd(1M) daemon must be stopped before running nisrestore.</p> <p>The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, nisrestore will exit with an error. The -f option will override this check and force the operation.</p> <p>The second synopsis will restore all of the directory objects contained in the <i>backup-dir</i>. Again, the server will be validated against the serving list for each of the directory objects in the <i>backup-dir</i>. If one of the objects in the <i>backup-dir</i> are not served by this server, nisrestore will exit with an error. The -f option will override this check and force the operation.</p>
OPTIONS	<pre> -a Restores all directory objects included in the <i>backup-dir</i> partition. -f Forces the restoration of a directory without the validation of the server in the directory object's serving list. -t Lists all directory objects contained in <i>backup-dir</i>. -v Verbose option. Additional output will be produced upon execution of the command. </pre>
OPERANDS	<pre> <i>backup-dir</i> The UNIX directory that contains the data files for the NIS+ directory objects to be restored. <i>directory</i> The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name. </pre>
EXAMPLES	<p>EXAMPLE 1 Restoring the <code>org_dir</code> directory object of the domain <code>foo.com</code> on a replica server from a local ufs partition named <code>/var/backup</code>.</p> <p>To restore the <code>org_dir</code> directory object of the domain <code>foo.com</code> on a replica server from a local ufs partition named <code>/var/backup</code>:</p> <pre> replica_server# nisrestore /var/backup org_dir.foo.com. </pre>

nisrestore(1M)

EXAMPLE 1 Restoring the `org_dir` directory object of the domain `foo.com` on a replica server from a local ufs partition named `/var/backup`. (Continued)

EXAMPLE 2 Forcing the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`.

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`:

```
replica_server# nisrestore -f -a /var/backup
```

EXAMPLE 3 Restoring the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects.

To restore the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects:

```
master_server# nisrestore /var/backup sub.foo.com. \  
org_dir.sub.foo.com. groups_dir.sub.foo.com.
```

EXIT STATUS 0 Successful completion.

1 An error occurred.

FILES `/backup-dir/backup_list`
This ascii file contains a list of all the objects contained in this *backup-dir* directory. This information can be displayed with the `-t` option.

`/backup-dir/directory-object`
A subdirectory that is created in the *backup-dir* which contains the directory-object backup.

`/backup-dir/directory-object/data`
A subdirectory that contains the data files that are part of the directory-object backup.

`/backup-dir/directory-object/last.upd`
This data file contains timestamp information about the directory-object.

`/backup-dir/directory-object/data.dict`
A NIS+ data dictionary for all of the objects contained in this directory-object backup.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nis+(1)`, `nisdefaults(1)`, `nisbackup(1M)`, `nissserver(1M)`, `rpc.nisd(1M)`, `share_nfs(1M)`, `nisfiles(4)`, `attributes(5)`

NOTES The `-a` option will attempt to restore all NIS+ objects contained in the `backup-dir`. If any of these objects are not served by the server, `nisrestore` will exit with an error. If the `backup-dir` contains objects that are not served by the server, `nisrestore` must be executed without the `-a` option and the specific directory objects listed.

The `-f` option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn't serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups.

The combination of options `-f` and `-a` should be used with caution, as no validation of the server serving the restored objects will be done.

New replicas can be quickly added to a namespace with the `nisrestore` command. The steps are as follows.

Configure the new replica on the master server (see `nissserver(1M)`):

```
master# nissserver -R -h replica
```

Kill the `rpc.nisd` server process on the new replica server:

```
replica# kill rpc.nisd-pid
```

Create a backup of the NIS+ database on the master, which will include the new replica information (see `nisbackup(1M)`). The `/backup` will need to be exported (see `share_nfs(1M)`) to the new replica:

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the `-f` option if `nisrestore` is unable to lookup the NIS+ objects being restored. The backup should be available through `nfs` or similar means (see `share_nfs(1M)`):

```
replica# nisrestore -f -a //nfs-mnt/backup
```

Restart the `rpc.nisd(1M)` process on the new replica, and the server will immediately be available for service.

nisserver(1M)

NAME	nisserver – set up NIS+ servers.														
SYNOPSIS	<pre> /usr/lib/nis/nisserver -r [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-g NIS+_groupname] [-l network_password] /usr/lib/nis/nisserver -M [-x] [-f] [-v] [-Y] -d NIS+_domain [-g NIS+_groupname] [-h NIS+_server_host] /usr/lib/nis/nisserver -R [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-h NIS+_server_host] </pre>														
DESCRIPTION	<p>The <code>nisserver</code> shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with <code>nisauthconf(1M)</code>, <code>nisserver</code> will set up a NIS+ server using those mechanisms. <code>nisauthconf(1M)</code> should be used before <code>nisserver</code>.</p> <p>When setting up a new domain, this script creates the NIS+ directories (including <code>groups_dir</code> and <code>org_dir</code>) and system table objects for the domain specified. It does not populate the tables. <code>nispopulate(1M)</code> must be used to populate the tables.</p>														
OPTIONS	<table border="0"> <tr> <td style="padding-right: 10px;">-d <i>NIS+_domain</i></td> <td>Specifies the name for the NIS+ domain. The default is your local domain.</td> </tr> <tr> <td style="padding-right: 10px;">-f</td> <td>Forces the NIS+ server setup without prompting for confirmation.</td> </tr> <tr> <td style="padding-right: 10px;">-g <i>NIS+_groupname</i></td> <td>Specifies the NIS+ group name for the new domain. This option is not valid with -R option. The default group is <code>admin.<domain></code>.</td> </tr> <tr> <td style="padding-right: 10px;">-h <i>NIS+_server_host</i></td> <td>Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, <code>hostx.xyz.sun.com.</code>) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.</td> </tr> <tr> <td style="padding-right: 10px;">-l <i>network_password</i></td> <td>Specifies the network password with which to create the credentials for the root master server. This option is <i>only</i> used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password.</td> </tr> <tr> <td style="padding-right: 10px;">-M</td> <td>Sets up the specified host as a master server. Make sure that <code>rpc.nisd(1M)</code> is running on the new master server before this command is executed.</td> </tr> <tr> <td style="padding-right: 10px;">-R</td> <td>Sets up the specified host as a replica server. Make sure that <code>rpc.nisd</code> is running on the new replica server.</td> </tr> </table>	-d <i>NIS+_domain</i>	Specifies the name for the NIS+ domain. The default is your local domain.	-f	Forces the NIS+ server setup without prompting for confirmation.	-g <i>NIS+_groupname</i>	Specifies the NIS+ group name for the new domain. This option is not valid with -R option. The default group is <code>admin.<domain></code> .	-h <i>NIS+_server_host</i>	Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, <code>hostx.xyz.sun.com.</code>) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.	-l <i>network_password</i>	Specifies the network password with which to create the credentials for the root master server. This option is <i>only</i> used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password.	-M	Sets up the specified host as a master server. Make sure that <code>rpc.nisd(1M)</code> is running on the new master server before this command is executed.	-R	Sets up the specified host as a replica server. Make sure that <code>rpc.nisd</code> is running on the new replica server.
-d <i>NIS+_domain</i>	Specifies the name for the NIS+ domain. The default is your local domain.														
-f	Forces the NIS+ server setup without prompting for confirmation.														
-g <i>NIS+_groupname</i>	Specifies the NIS+ group name for the new domain. This option is not valid with -R option. The default group is <code>admin.<domain></code> .														
-h <i>NIS+_server_host</i>	Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, <code>hostx.xyz.sun.com.</code>) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.														
-l <i>network_password</i>	Specifies the network password with which to create the credentials for the root master server. This option is <i>only</i> used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password.														
-M	Sets up the specified host as a master server. Make sure that <code>rpc.nisd(1M)</code> is running on the new master server before this command is executed.														
-R	Sets up the specified host as a replica server. Make sure that <code>rpc.nisd</code> is running on the new replica server.														

-r	Sets up the server as a root master server. Use the -R option to set up a root replica server.
-v	Runs the script in verbose mode.
-x	Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
-Y	Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.

USAGE Use the first synopsis of the command (-r) to set up a root master server. To run the command, you must be logged in as super-user on the server machine.

Use the second synopsis of the command (-M) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see `nisclient(1M)`) and have the `rpc.nisd(1M)` daemon running.

Use the third synopsis of the command (-R) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the `rpc.nisd` daemon running.

EXAMPLES **EXAMPLE 1** Setting up servers.

To set up a root master server for domain `sun.com.`:

```
root_server# /usr/lib/nis/nisserver -r -d sun.com.
```

For the following examples make sure that the new servers are NIS+ clients and `rpc.nisd` is running on these hosts before executing `nisserver`. To set up a replica server for domain `sun.com.` on host `sunreplica`:

```
root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep
```

To set up a non-root master server for domain `xyz.sun.com.` on host `sunxyz` with the NIS+ groupname as `admin-mgr.xyz.sun.com.`:

```
root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz \
-g admin-mgr.xyz.sun.com.
```

To set up a non-root replica server for domain `xyz.sun.com.` on host `sunabc`:

```
sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

nisserver(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO nis+(1), nisgrpadm(1), nismkdir(1), nisaddcred(1M), nisauthconf(1M), nisclient(1M), nisinit(1M), nispopulate(1M), nisprefadm(1M), nissetup(1M), rpc.nisd(1M), attributes(5)

NAME	nissetup – initialize a NIS+ domain				
SYNOPSIS	<code>/usr/lib/nis/nissetup [-Y] [domain]</code>				
DESCRIPTION	<p>nissetup is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named <i>domain</i>. This domain should already exist prior to executing this command (see nismkdir(1) and nisinit(1M)).</p> <p>A NIS+ domain consists of a NIS+ directory and its subdirectories: <i>org_dir</i> and <i>groups_dir</i>. <i>org_dir</i> stores system administration information and <i>groups_dir</i> stores information for group access control.</p> <p>nissetup creates the subdirectories <i>org_dir</i> and <i>groups_dir</i> in <i>domain</i>. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, nissetup creates the default tables that NIS+ serves. These are <i>auto_master</i>, <i>auto_home</i>, <i>bootparams</i>, <i>cred</i>, <i>ethers</i>, <i>group</i>, <i>hosts</i>, <i>mail_aliases</i>, <i>netmasks</i>, <i>networks</i>, <i>passwd</i>, <i>protocols</i>, <i>rpc</i>, <i>services</i>, and <i>timezone</i>. The nissetup script uses the nistbladm(1) command to create these tables. The script can be easily customized to add site specific tables that should be created at setup time.</p> <p>This command is normally executed just once per domain.</p>				
OPTIONS	<p>-Y Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWnisu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnisu				
SEE ALSO	nis+(1), nismkdir(1), nistbladm(1), nisaddent(1M), nisinit(1M), nisserver(1M), attributes(5)				
NOTES	<p>While this command creates the default tables, it does not initialize them with data. This is accomplished with the nisaddent(1M) command.</p> <p>It is easier to use the nisserver(1M) script to create subdirectories and the default tables.</p>				

nisshowcache(1M)

NAME nisshowcache – NIS+ utility to print out the contents of the shared cache file

SYNOPSIS /usr/lib/nis/nisshowcache [-v]

DESCRIPTION nisshowcache prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, nisshowcache only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by nis_cachemgr(1M).

OPTIONS -v Verbose mode. Print out the contents of each directory object, including information on the server name and its universal addresses.

FILES /var/nis/NIS_SHARED_DIRCACHE

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	nisstat – report NIS+ server statistics																
SYNOPSIS	<code>/usr/lib/nis/nisstat [-H <i>host</i>] [<i>directory</i>]</code>																
DESCRIPTION	<p>The <code>nisstat</code> command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. Requesting a statistic from a server that does not support that statistic is never fatal, it simply returns “unknown statistic.”</p> <p>By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If <i>directory</i> is specified, servers for that directory are queried.</p> <p>Supported statistics for this release are as follows:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>root server</i></td> <td>This reports whether the server is a root server.</td> </tr> <tr> <td><i>NIS compat mode</i></td> <td>This reports whether the server is running in NIS compat mode.</td> </tr> <tr> <td><i>DNS forwarding in NIS mode</i></td> <td>This reports whether the server in NIS compat mode will forward host lookup calls to DNS.</td> </tr> <tr> <td><i>security level</i></td> <td>This reports the security level of this server.</td> </tr> <tr> <td><i>serves directories</i></td> <td>This lists the directories served by this server.</td> </tr> <tr> <td><i>Operations</i></td> <td>This statistic returns results in the form: OP=<i>opname</i> : C=<i>calls</i> : E=<i>errors</i> : T=<i>micros</i> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running, <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.</td> </tr> <tr> <td><i>Directory Cache</i></td> <td>This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td> </tr> <tr> <td><i>Group Cache</i></td> <td>This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td> </tr> </table>	<i>root server</i>	This reports whether the server is a root server.	<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.	<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.	<i>security level</i>	This reports the security level of this server.	<i>serves directories</i>	This lists the directories served by this server.	<i>Operations</i>	This statistic returns results in the form: OP= <i>opname</i> : C= <i>calls</i> : E= <i>errors</i> : T= <i>micros</i> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running, <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.	<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.	<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.
<i>root server</i>	This reports whether the server is a root server.																
<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.																
<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.																
<i>security level</i>	This reports the security level of this server.																
<i>serves directories</i>	This lists the directories served by this server.																
<i>Operations</i>	This statistic returns results in the form: OP= <i>opname</i> : C= <i>calls</i> : E= <i>errors</i> : T= <i>micros</i> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running, <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.																
<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																
<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																

nisstat(1M)

Static Storage This statistic reports the number of bytes the server has allocated for its static storage buffers.

Dynamic Storage This statistic reports the amount of heap the server process is currently using.

Uptime This statistic reports the time since the service has been running.

OPTIONS -H *host* Normally all servers for the directory are queried. With this option, only the machine named *host* is queried. If the named machine does not serve the directory, no statistics are returned.

ENVIRONMENT VARIABLES NIS_PATH If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nisdefaults(1)`, `nisopaccess(1)`, `attributes(5)`

NOTES Per-server and per-directory access restrictions may apply; see `nisopaccess(1)`. `nisstat` uses `NIS_STATUS`.

NAME	nispdkeys – update the public keys in a NIS+ directory object
SYNOPSIS	<pre>/usr/lib/nis/nispdkeys [-a -C] [-H <i>host</i>] [<i>directory</i>]</pre> <pre>/usr/lib/nis/nispdkeys -s [-a -C] -H <i>host</i></pre>
DESCRIPTION	<p>This command updates the public keys in an NIS+ directory object. When the public key(s) for a NIS+ server are changed, <code>nispdkeys</code> reads a directory object and attempts to get the public key data for each server of that directory. These keys are placed in the directory object and the object is then modified to reflect the new keys. If <i>directory</i> is present, the directory object for that directory is updated. Otherwise the directory object for the default domain is updated. The new key must be propagated to all directory objects that reference that server.</p> <p>On the other hand, <code>nispdkeys -s</code> gets a list of all the directories served by <i>host</i> and updates those directory objects. This assumes that the caller has adequate permission to change all the associated directory objects. The list of directories being served by a given server can also be obtained by <code>nisstat(1M)</code>. Before you do this operation, make sure that the new address/public key has been propagated to all replicas. If multiple authentication mechanisms are configured using <code>nisauthconf(1M)</code>, then the keys for those mechanisms will also be updated or cleared.</p>
OPTIONS	<p>-a Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <code>getipnodebyname(3SOCKET)</code> on this machine. The <code>/etc/nsswitch.conf</code> file must point to the correct source for <i>ipnodes</i> and <i>hosts</i> for this resolution to work.</p> <p>-C Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.</p> <p>-H <i>host</i> Limit key changes only to the server named <i>host</i>. If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.</p> <p>-s Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to change all the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will be notified. If the <code>rpc.nisd</code> on <i>host</i> cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke <code>nispdkeys</code> multiple times (as in the first synopsis), once per NIS+ directory that it serves.</p>

nisupdkeys(1M)

EXAMPLES

EXAMPLE 1 Using nisupdkeys

The following example updates the keys for servers of the *foo.bar*. domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host *fred* which serves the *foo.bar*. domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host *wilma* in the *foo.bar*. directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host *wilma*.

```
example% nisupdkeys -s -H wilma
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO

`chkey(1)`, `niscat(1)`, `nisaddcred(1M)`, `nisauthconf(1M)`, `nisstat(1M)`, `getipnodebyname(3SOCKET)`, `nis_objects(3NSL)`, `attributes(5)`

NOTES

The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the `niscat(1)` command using the `-o` option.

This command does not update the directory objects stored in the `NIS_COLD_START` file on the NIS+ clients.

If a server is also the root master server, then `nisupdkeys -s` cannot be used to update the root directory.

NAME	nlsadmin – network listener service administration						
SYNOPSIS	<pre> /usr/sbin/nlsadmin -x /usr/sbin/nlsadmin [options] net_spec /usr/sbin/nlsadmin [options] -N port_monitor_tag /usr/sbin/nlsadmin -V /usr/sbin/nlsadmin -c cmd -o streamname [-p modules] [-A address -D] [-R prognum : versnum] </pre>						
DESCRIPTION	<p>nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process “listens” to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification.</p> <p>nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively.</p> <p><i>net_spec</i> represents a particular listener process. Specifically, <i>net_spec</i> is the relative path name of the entry under /dev for a given network (that is, a transport provider). <i>address</i> is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, <i>address</i> is interpreted as the symbolic ASCII representation of the transport address. An <i>address</i> preceded by \x will let you enter an address in hexadecimal notation. Note that <i>address</i> must appear as a single word to the shell, thus it must be quoted if it contains any blanks.</p> <p>Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.</p>						
OPTIONS	<p>nlsadmin may be used with the following combinations of options and arguments:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">-x</td> <td>Report the status of all of the listener processes installed on this machine.</td> </tr> <tr> <td style="padding-right: 20px;"><i>net_spec</i></td> <td>Print the status of the listener process for <i>net_spec</i> .</td> </tr> <tr> <td style="padding-right: 20px;">-q <i>net_spec</i></td> <td>Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a</td> </tr> </table>	-x	Report the status of all of the listener processes installed on this machine.	<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .	-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a
-x	Report the status of all of the listener processes installed on this machine.						
<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .						
-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a						

nlsadmin(1M)

	status of 0; if no process is active, the exit code will be 1; the exit code will be greater than 1 in case of error.
<code>-v net_spec</code>	Print a verbose report on the servers associated with <i>net_spec</i> , giving the service code, status, command, and comment for each. It also specifies the <code>uid</code> the server will run as and the list of modules to be pushed, if any, before the server is started.
<code>-z service_code net_spec</code>	Print a report on the server associated with <i>net_spec</i> that has service code <i>service_code</i> , giving the same information as in the <code>-v</code> option.
<code>-q -z service_code net_spec</code>	Query the status of the service with service code <i>service_code</i> on network <i>net_spec</i> , and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.
<code>-l address net_spec</code>	Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the <code>-a</code> option, below). If <i>address</i> is just a dash (" - "), <code>nlsadmin</code> reports the address currently configured, instead of changing it. A change of address takes effect immediately.
<code>-t address net_spec</code>	Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the <code>-l</code> option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the <code>-a</code> option, below).
<code>-i net_spec</code>	Initialize an instance of the listener for the network specified by <i>net_spec</i> ; that is, create and initialize the files required by the listener as well as starting that instance of

the listener. Note that a particular instance of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.

-a *service_code*

```
[ -p modules ] [ -w name ] -c cmd -y
comment net_spec
```

Add a new service to the list of services available through the indicated listener. *service_code* is the code for the service, *cmd* is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and *comment* is a brief (free-form) description of the service for use in various reports. Note that *cmd* must appear as a single word to the shell; if arguments are required, the *cmd* and its arguments must be enclosed in quotation marks. The *comment* must also appear as a single word to the shell. When a service is added, it is initially enabled (see the -e and -d options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nlps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the -p option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the -w option is specified, then *name* is interpreted as the user name from */etc/passwd* that the listener should look up. From the user name, the listener obtains

<p><i>-w service_code net_spec</i></p>	<p>the user ID, the group ID(s), and the home directory for use by the server. If <i>-w</i> is not specified, the default is to use the user name <i>listen</i>.</p>
<p><i>-a service_code net_spec</i></p>	<p>A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.</p>
<p><i>-r service_code net_spec</i></p>	<p>Remove the entry for the <i>service_code</i> from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.</p>
<p><i>-e service_code net_spec</i> <i>-d service_code net_spec</i></p>	<p>Enable or disable (respectively) the service indicated by <i>service_code</i> for the specified network. The service must previously have been added to the listener for that network (see the <i>-a</i> option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.</p>
<p><i>-s net_spec</i> <i>-k net_spec</i></p>	<p>Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the <i>-i</i> option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.</p>
<p>Under the Service Access Facility, it is possible to have multiple instances of the listener on a single <i>net_spec</i>. In any of the above commands, the option <i>-N port_monitor_tag</i> may be used in place of the <i>net_spec</i> argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the <i>-N</i> option is not specified (that is, the <i>net_spec</i> is specified in the invocation), then it will be assumed that the last component of the <i>net_spec</i> represents the tag of the listener for which the operation is destined. In other words, it is assumed</p>	

that there is at least one listener on a designated *net_spec*, and that its tag is identical to the last component of the *net_spec*. This listener may be thought of as the primary, or default, listener for a particular *net_spec*.

`nlsadmin` is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

`-V`

Write the current version number of the listener's administrative file to the standard output. It is used as part of the `sacadm` command line when `sacadm` adds a port monitor to the system.

`-c cmd | -o streamname [-p modules] [-A address | -D] [-R program : versnum]`

Format the port monitor-specific information to be used as an argument to `pmadm(1M)`

The `-c` option specifies the full path name of the server and its arguments. *cmd* must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The `-o` option specifies the full path name of a FIFO or named STREAM through which a standing server is actually receiving the connection.

If the `-p` option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. *modules* must be a comma-separated list, with no white space included.

If the `-A` option is specified, then *address* will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the `-D` option.

If the `-D` option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the `-R` option to register the dynamically assigned address with the `rpcbinder`. This option may not be used in conjunction with the `-A` option.

When the `-R` option is specified, the service is an RPC service whose address, program number, and version number should be registered with the `rpcbinder` for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. *program* and *versnum* are the program number and version number, respectively, of the RPC service.

`nlsadmin` may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

nlsadmin(1M)

The options specific to the Service Access Facility may not be used together with any other options.

ERRORS If successful, `nlsadmin` exits with a status of 0. If `nlsadmin` fails for any reason, it exits with a status greater than or equal to 2. See `-q` option for a return status of 1.

System Administration Guide, Volume 1

NOTES Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

NAME	nscd – name service cache daemon								
SYNOPSIS	<code>/usr/sbin/nscd [-f <i>configuration-file</i>] [-g] [-e <i>cachename</i>, yes no] [-i <i>cachename</i>]</code>								
DESCRIPTION	<p>nscd is a process that provides a cache for the most common name service requests. It starts up during multi-user boot. The default <i>configuration-file</i> <code>/etc/nscd.conf</code> determines the behavior of the cache daemon. See <code>nscd.conf(4)</code>.</p> <p>nscd provides caching for the <code>passwd(4)</code>, <code>group(4)</code>, <code>hosts(4)</code>, <code>ipnodes(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> databases through standard <code>libc</code> interfaces, such as <code>gethostbyname(3NSL)</code>, <code>getipnodebyname(3SOCKET)</code>, <code>gethostbyaddr(3NSL)</code>, and others. Each cache has a separate time-to-live for its data; modifying the local database (<code>/etc/hosts</code>, <code>/etc/resolv.conf</code>, and so forth) causes that cache to become invalidated upon the next call to nscd. The shadow file is specifically not cached. <code>getspnam(3C)</code> calls remain uncached as a result.</p> <p>nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.</p> <p>In order to preserve NIS+ security, the startup script for nscd (<code>/etc/init.d/nscd</code>) checks the permissions on the <code>passwd</code> table if NIS+ is being used. If this table cannot be read by unauthenticated users, then nscd will make sure that any encrypted password information returned from the NIS+ server is supplied only to the owner of that password.</p>								
OPTIONS	<p>Several of the options described below require a <i>cachename</i> specification. Supported values are <code>passwd</code>, <code>group</code>, <code>hosts</code>, <code>ipnodes</code>, <code>exec_attr</code>, <code>prof_attr</code>, and <code>user_attr</code>.</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>-f <i>configuration-file</i></code></td> <td>Causes nscd to read its configuration data from the specified file.</td> </tr> <tr> <td><code>-g</code></td> <td>Prints current configuration and statistics to standard output. This is the only option executable by non-root users.</td> </tr> <tr> <td><code>-e <i>cachename</i>, yes no</code></td> <td>Enables or disables the specified cache.</td> </tr> <tr> <td><code>-i <i>cachename</i></code></td> <td>Invalidate the specified cache.</td> </tr> </table>	<code>-f <i>configuration-file</i></code>	Causes nscd to read its configuration data from the specified file.	<code>-g</code>	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.	<code>-e <i>cachename</i>, yes no</code>	Enables or disables the specified cache.	<code>-i <i>cachename</i></code>	Invalidate the specified cache.
<code>-f <i>configuration-file</i></code>	Causes nscd to read its configuration data from the specified file.								
<code>-g</code>	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.								
<code>-e <i>cachename</i>, yes no</code>	Enables or disables the specified cache.								
<code>-i <i>cachename</i></code>	Invalidate the specified cache.								
EXAMPLES	<p>EXAMPLE 1 Stopping and restarting the nscd daemon.</p> <pre>example# /etc/init.d/nscd stop</pre> <pre>example# /etc/init.d/nscd start</pre>								
FILES	<code>/etc/nscd.conf</code> determines the behavior of the cache daemon

NAME	nslookup – query name servers interactively																						
SYNOPSIS	nslookup [- option]... <i>host</i> [<i>server</i>] nslookup [- option]... - [<i>server</i>] nslookup																						
DESCRIPTION	nslookup sends queries to Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to contact servers for information about various hosts and domains or to display a list of hosts in a domain. Non-interactive mode is used to display just the name and requested information for a host or domain.																						
OPTIONS	<p><i>-option</i> Set the permissible options, as shown in the following list. These are the same options that the <code>set</code> command supports in interactive mode (see <code>set</code> in the <code>Commands</code> section for more complete descriptions).</p> <table border="0"> <tr> <td style="padding-right: 20px;">all</td> <td>List the current settings</td> </tr> <tr> <td>class=<i>classname</i></td> <td>Restrict search according to the specified class</td> </tr> <tr> <td>d2</td> <td>Set exhaustive debug mode on</td> </tr> <tr> <td>nod2</td> <td>Set exhaustive debug mode off</td> </tr> <tr> <td>debug</td> <td>Set debug mode on</td> </tr> <tr> <td>nodebug</td> <td>Set debug mode off</td> </tr> <tr> <td>defname</td> <td>Set domain-appending mode on</td> </tr> <tr> <td>nodefname</td> <td>Set domain-appending mode off</td> </tr> <tr> <td>domain=<i>string</i></td> <td>Establish the appendable domain</td> </tr> <tr> <td>ignoretc</td> <td>Set it to ignore packet truncation errors</td> </tr> <tr> <td>noignoretc</td> <td>Set it to acknowledge packet truncation errors</td> </tr> </table>	all	List the current settings	class= <i>classname</i>	Restrict search according to the specified class	d2	Set exhaustive debug mode on	nod2	Set exhaustive debug mode off	debug	Set debug mode on	nodebug	Set debug mode off	defname	Set domain-appending mode on	nodefname	Set domain-appending mode off	domain= <i>string</i>	Establish the appendable domain	ignoretc	Set it to ignore packet truncation errors	noignoretc	Set it to acknowledge packet truncation errors
all	List the current settings																						
class= <i>classname</i>	Restrict search according to the specified class																						
d2	Set exhaustive debug mode on																						
nod2	Set exhaustive debug mode off																						
debug	Set debug mode on																						
nodebug	Set debug mode off																						
defname	Set domain-appending mode on																						
nodefname	Set domain-appending mode off																						
domain= <i>string</i>	Establish the appendable domain																						
ignoretc	Set it to ignore packet truncation errors																						
noignoretc	Set it to acknowledge packet truncation errors																						
OPERANDS	<p><i>host</i> Inquires about the specified <i>host</i>. In this non-interactive command format, nslookup Does not prompt for additional commands.</p> <p>– Causes nslookup to prompt for more information, such as host names, before sending one or more queries.</p> <p><i>server</i> Directs inquiries to the name server specified here in the command line rather than the one read from the <code>/etc/resolv.conf</code> file (see <code>resolv.conf(4)</code>). <i>server</i> can be either a name or an Internet address. If the specified host cannot be reached, nslookup resorts to using the name server specified in <code>/etc/resolv.conf</code>.</p>																						
Non-interactive Mode	Non-interactive mode is selected when the name or Internet address of the host to be looked up is given as the first argument.																						

nslookup(1M)

Within non-interactive mode, space-separated options can be specified. They must be entered before the host name, to be queried. Each option must be prefixed with a hyphen.

For example, to request extensive host information and to set the timeout to 10 seconds when inquiring about *gypsy*, enter:

```
example% nslookup-query=hinfo-timeout=10gypsy
```

To avoid repeated entry of an option that you almost always use, place a corresponding `set` command in a `.nslookuprc` file located inside your home directory. (See `Commands` for more information about `set`.) The `.nslookuprc` file can contain several `set` commands if each is followed by a RETURN.

Entering and Leaving Interactive Mode

Interactive mode is selected when

- No arguments are supplied.
- A '-' (hyphen) character is supplied as the *host* argument.

To exit from an interactive `nslookup` session, type `Control-d` or type the command `exit` followed by RETURN.

Supported Command Interactions

The commands associated with interactive mode are subject to various limitations and run-time conventions.

The maximum length of a command line is 255 characters. When the RETURN key is pressed, command-line execution begins. While a command is running, its execution can be interrupted by typing `Control-c`.

The first word entered on the command line must be the name of a `nslookup` command unless you wish to enter the name of a host to inquire about. Any unrecognized command is handled as a host name to inquire about. To force a command to be treated as a host name to be inquired about, precede it with a backslash character.

Commands

`exit`

Exit the `nslookup` program.

`help`

`?`

Display a brief summary of commands.

`host [server]`

Look up information for *host* using the current default server, or using *server* if it is specified.

If the *host* supplied is an Internet address and the query type is `A` or `1PTR`, the name of the host is returned. If the *host* supplied is a name and it does not have a trailing

period, the default domain name is appended to the name. (This behavior depends on the state of the `set` options `domain`, `srchlist`, `defname`, and `search`).

To look up a host that is not in the current domain, append a period to the name.

`finger [name] [>> filename]`

Connect with the finger server on the current host, which is defined by the most recent successful host lookup.

If no `name` value is specified, a list of login account names on the current host is generated.

Similar to a shell command interpreter, output can be redirected to a file using the usual redirection symbols: `>` and `>>`.

`ls [-options] domain [>> filename]`

List the information available for `domain`, optionally creating or appending to `filename`. The default output contains host names and their Internet addresses.

Output can be redirected to `filename` using the `>` and `>>` redirection symbols. When output is directed to a file, hash marks are shown for every 50 records received from the server. The permissible values for `options` are:

<code>a</code>	Lists aliases of hosts in the domain. This is a synonym for the command <code>ls-tCNAME</code> .
<code>d</code>	Lists all records for the domain. This is a synonym for the command <code>ls-tANY</code> .
<code>h</code>	Lists CPU and operating system information for the domain. This is a synonym for the command <code>ls-tHINFO</code> .
<code>s</code>	Lists well-known services of hosts in the domain. This is a synonym for the command <code>ls-tWKS</code> .
<code>t querytype-value</code>	lists all records of the specified type (see <code>querytype</code> within the discussion of the <code>set</code> command).

`set token=value`

`set keyword`

Establish a preferred mode of search operation. Permissible `token` and `keyword` values are:

<code>all</code>	Display the current values of frequently-used options. Information about the current default server and host is also displayed.
------------------	---

<code>cl[ass]=classname</code>	Limit the search according to the protocol group (<code>classname</code>) for which lookup information is desired. Permissible <code>classname</code> values are:
--------------------------------	---

nslookup(1M)

	ANY	A wildcard selecting all classes
	IN	The Internet class (the default)
	CHAOS	The Chaos class.
	HESIOD	The MIT Athena Hesiod class.
d2 nod2		Enable or disable exhaustive debugging mode. Essentially all fields of every packet are displayed. By default, this option is disabled.
deb[ug] nodeb[ug]		Enable or disable debugging mode. When debugging mode is enabled, much more information is produced about the packet sent to the server and the resulting answer. By default, this option is disabled.
def[name] nodef[name]		Enable or disable appending the default domain name to a single-component lookup request (one that lacks a dot). By default, this option is enabled for <code>nslookup</code> . The default value for the domain name is the value given in <code>/etc/resolv.conf</code> , unless: there is an environmental value for <code>LOCALDOMAIN</code> when <code>nslookup</code> is run; a recent value has been specified through the <code>srchlist</code> command or the <code>set domain</code> command.
do[main]= <i>string</i>		Change the default domain name to be appended to all lookup requests to <i>string</i> . For this option to have any effect, the <code>defname</code> option must also be enabled and the <code>search</code> option must be set in a compatible way. The domain search list contains the parents of the default domain if it has at least two components in its name. For example, if the default domain is <code>CC.Berkeley.EDU</code> , the search list is <code>CC.Berkeley.EDU</code> and <code>Berkeley.EDU</code> . Use the <code>set srchlist</code> command to specify a different list. Use the <code>set all</code> command to display the list.
ignoretc noignoretc		Ignore packet truncation errors. By default, this option is disabled.

```
srch[list]=name1/name2/. . .
```

Change the default domain name to *name1* and the domain search list to *name1*, *name2*, etc. A maximum of 6 names can be specified, along with slash characters to separate them. For example,

```
example%
set srchlist=lcs.MIT.EDU/ai.MIT.EDU/MIT.EDU
```

sets the domain to `lcs.MIT.EDU` and the search list to all three names. This command overrides the default domain name and search list of the `set domain` command. Use the `set all` command to display the list.

```
search
```

```
nosearch
```

Enable or disable having the domain names in the domain search list appended to the request, generating a series of lookup queries if necessary until an answer is received. To take effect, the lookup request must contain at least one dot (period); yet it must not contain a trailing period. By default, this option is enabled.

```
po[rt]=value
```

Specify the default TCP/UDP name server port. By default, this value is 53.

```
q[querytype]=value
```

```
ty[pe]=value
```

Change the type of information returned from a query to one of:

A	The Internet address of the host
CNAME	The canonical name for an alias
HINFO	The host CPU and operating system type
MD	The mail destination
MX	The mail exchanger
MB	The mailbox domain name
MG	The mail group member
MINFO	The mailbox or mail list information
NS	The name server
PTR	The host name if the query is in the form of an Internet address; otherwise the pointer to other information
SOA	The domain's start-of-authority information
TXT	The text information
UINFO	The user information
WKS	The supported well-known services (Other types specified in the <i>RFC 1035</i> document are valid, but they are not as useful.)

nslookup(1M)

`recurse`
`norecurse`
Enable or disable having to query other name servers before abandoning a search. By default, this feature is enabled.

`ret[ry]=count`
Set the maximum number of times to retry a request before abandoning a search. When a reply to a request is not received within a certain amount of time (changed with `set timeout`), the timeout period is doubled and the request is resent. The retry value controls how many times a request is resent before the request is aborted. The default for `count` is 4.

`ro[ot]=host`
Change the name of the root server to `host`. This affects the `root` command. The default root server is `ns.internic.net`.

`t[imeout]=interval`
Change the amount of time to wait for a reply to `interval` seconds. Each retry doubles the timeout period. The default `interval` is 5 seconds.

`vc`
`novc`
Enable or disable the use of a virtual circuit when sending requests to the server. By default, this feature is disabled.

`root`
Change the default server to the server for the root of the domain name space. Currently, the host `ns.internic.net` is used; this command is a synonym for server `ns.internic.net`. The name of the root server can be changed with the `set root` command.

`server domain`
`lserver domain`
Change the default server to `domain`. `lserver` uses the initial server to look up information about `domain` while `server` uses the current default server. If an authoritative answer can not be found, the names of servers that might have the answer are returned.

`view filename`
Sort the output of previous `ls` command(s) and display it one text screenful at a time, similar to `more(1)`.

EXAMPLES **EXAMPLE 1** Searching the Internet domain namespace.

To effectively search the Internet domain namespace, it helps to know its structure. At present, the Internet domain name-space is tree-structured, with one top level domain for each country except the U.S.A. There are also some traditional top level domains, not explicitly tied to any particular country. These include:

COM	Commercial establishments
EDU	Educational institutions

EXAMPLE 1 Searching the Internet domain namespace. (Continued)

```
ORG      Not-for-profit organizations
GOV      Government agencies
MIL      MILNET hosts
```

If you are looking for a specific host, you need to know something about the host's organization in order to determine the top-level domain that it belongs to. For instance, if you want to find the Internet address of a machine at UCLA, do the following:

- Connect with the root server using the `root` command. The root server of the name space has knowledge of the top-level domains.
- Since UCLA is a university, its domain name is `ucla.edu`. Connect with a server for the `ucla.edu` domain with the command `server ucla.edu`. The response produces the names of hosts that act as servers for that domain. Note: the root server does not have information about `ucla.edu`, but knows the names and addresses of hosts that do. Once located by the root server, all future queries will be sent to the UCLA name server.
- To request information about a particular host in the domain (for instance, `locus`), just type the host name. To request a listing of hosts in the UCLA domain, use the `ls` command. The `ls` command requires a domain name (in this case, `ucla.edu`) as an argument.

If you are connected with a name server that handles more than one domain, all lookups for host names must be fully specified with its domain. For instance, the domain `harvard.edu` is served by `seismo.css.gov`, which also services the `css.gov` and `cornell.edu` domains. A lookup request for the host `aiken` in the `harvard.edu` domain must be specified as `aiken.harvard.edu`. However, the `set domain=name` and `set defname` commands can be used to automatically append a domain name to each request.

After a successful lookup of a host, use the `finger(1)` command to see who is on the system, or to finger a specific person. (`finger` requires the type to be `A`.)

To get other information about the host, use the `set querytype=value` command to change the type of information desired and request another lookup.

ENVIRONMENT VARIABLES

```
HOSTALIASES  References the file containing host aliases
LOCALDOMAIN  Overrides default domain
```

EXIT STATUS

The process returns the following values:

```
0          On success.
1          On failure.
```

nslookup(1M)

FILES /etc/resolv.conf

Mockapetris, Paul, *Domain Names - Concepts and Facilities*, RFC 1034, Network Information Center, SRI International, Menlo Park, Calif., November 1987.

Mockapetris, Paul, *Domain Names - Implementation and Specification*, RFC 1035, Network Information Center, SRI International, Menlo Park, Calif., November 1987.

DIAGNOSTICS If the lookup request is successful, an error message is produced. Possible errors are:

Timed out	The server did not respond to a request after a certain amount of time (changed with <code>set timeout=value</code>) and a certain number of retries (changed with <code>set retry=value</code>).
No response from server	No name server is running on the server machine.
No records	The server does not have resource records of the current query type for the host, although the host name is valid. The query type is specified with the <code>set querytype</code> command.
Non-existent domain	The host or domain name does not exist.
Connection refused Network is unreachable	The connection to the name or finger server can not be made at the current time. This error commonly occurs with <code>ls</code> and <code>finger</code> requests.

nslookup(1M)

Server failure

The name server found an internal inconsistency in its database and could not return a valid answer.

Refused

The name server refused to service the request.

Format error

The name server found that the request packet was not in the proper format. This may indicate an error in nslookup.

nstest(1M)

NAME nstest – DNS test shell

SYNOPSIS **nstest** [-d] [-i] [-r] [-v] [-p *port*] [*inet_addr* [*logfile*]]

DESCRIPTION nstest is an interactive DNS test program. Queries are formed and sent by user command; any reply received is printed on the standard output. *inet_addr* is the Internet address of the DNS resolver to which nstest should send its queries. If *inet_addr* is not included, nstest first tries to contact a DNS server on the local host; if that fails, it tries the servers listed in the /etc/resolv.conf file. If a *logfile* is supplied, nstest uses it to log the queries sent and replies received.

OPTIONS

- d Causes nstest to create a file named ns_packet.dump (if it does not exist) and write into it a raw (binary) copy of each packet sent. If ns_packet.dump does exist, nstest will truncate it.
- i Sets the RES_IGNTC flag on the queries it makes. See resolver(3RESOLV) for a description of the RES_IGNTC flag.
- r Turns off the RES_RECURSE flag on the queries it makes. See resolver(3RESOLV) for a description of the RES_RECURSE flag.
- v Turns on the RES_USEVC and RES_STAYOPEN flags on the res_send () calls made. See resolver(3RESOLV) for a description of the RES_USEVC and RES_STAYOPEN flags.
- p Causes nstest to use the supplied *port* instead of the default name server port.

USAGE When nstest starts, it prints a prompt (">") and waits for user input. DNS queries are formed by typing a *key letter* followed by the appropriate *argument*. Each *key letter* results in a call to res_mkquery () with *op* set to either IQUERY or QUERY and *type* set to one of the type values (defined in <arpa/nameser.h>). (Any other key letter than those listed below causes nstest to print a summary of the following table.)

Key Letter & Argument	Op	Type
<i>ahost</i>	QUERY	T_A
<i>Aaddr</i>	IQUERY	T_A
<i>Buser</i>	QUERY	T_MG
<i>buser</i>	QUERY	T_MB
<i>chost</i>	QUERY	T_CNAME
<i>fhost</i>	QUERY	T_UINFO

<i>Ggid</i>	IQUERY	T_GID
<i>ghost</i>	QUERY	T_GID
<i>hhost</i>	QUERY	T_HINFO
<i>ihost</i>	QUERY	T_MINFO
<i>Mhost</i>	QUERY	T_MAILB
<i>mhost</i>	QUERY	T_MX
<i>nhost</i>	QUERY	T_NS
<i>phost</i>	QUERY	T_PTR
<i>rhost</i>	QUERY	T_MR
<i>shost</i>	QUERY	T_SOA
<i>Thost</i>	QUERY	T_TXT
<i>Uuid</i>	IQUERY	T_UID
<i>uhost</i>	QUERY	T_UID
<i>whost</i>	QUERY	T_WKS
<i>xhost</i>	QUERY	T_AXFR

After the query is successfully formed, `res_send()` is called to send it and wait for a reply. `nstest` then prints the following on the standard output:

- a summary of the request and reply packets, including the `HEADER` structure (defined in `<arpa/nameser.h>`) used in the request
- the question being asked of the name server
- an enumeration of the name server(s) being polled
- a summary of the `HEADER` structure received in the reply
- the question the name server answered
- the answer itself

EXAMPLES

EXAMPLE 1 Fetching the address of host `playground.sun.com` from the Sun name server.

To fetch the address of host `playground.sun.com` from the Sun name server, the user would enter:

```
$ nstest 192.9.5.1
> aplayground.sun.com
```

The utility `nstest` would return the following:

```
res_mkquery(0, playground.sun.com, 1, 1)
res_send()
```

nstest(1M)

EXAMPLE 1 Fetching the address of host playground.sun.com from the Sun name server. (Continued)

```
HEADER:
    opcode = QUERY, id = 1, rcode = NOERROR
    header flags: rd
    qdcount = 1, ancount = 0, nscount = 0, arcount = 0

QUESTIONS:
    playground.sun.com, type = A, class = IN

Querying server (# 1) address = 192.9.5.1
got answer:
HEADER:
    opcode = QUERY, id = 1, rcode = NOERROR
    header flags: qr aa rd ra
    qdcount = 1, ancount = 1, nscount = 0, arcount = 0

QUESTIONS:
    playground.sun.com, type = A, class = IN
ANSWERS:
    playground.sun.com
    type = A, class = IN, ttl = 1 day, dlen = 4
    internet address = 192.9.5.5
```

EXAMPLE 2 Looking up a PTR record.

To look up a PTR record, enter:

```
$ nstest 192.9.5.1
> p5.5.9.192.in-addr.arpa
```

The utility nstest would return the following:

```
res_mkquery(0, 5.5.9.192.in-addr.arpa, 1, 12)
res_send()
HEADER:
    opcode = QUERY, id = 2, rcode = NOERROR
    header flags: rd
    qdcount = 1, ancount = 0, nscount = 0, arcount = 0

QUESTIONS:
    5.5.9.192.in-addr.arpa, type = PTR, class = IN

Querying server (# 1) address = 192.9.5.1
got answer:
HEADER:
    opcode = QUERY, id = 2, rcode = NOERROR
    header flags: qr aa rd ra
    qdcount = 1, ancount = 1, nscount = 0, arcount = 0

QUESTIONS:
    5.5.9.192.in-addr.arpa, type = PTR, class = IN

ANSWERS:
    5.5.9.192.in-addr.arpa
```

EXAMPLE 2 Looking up a PTR record. *(Continued)*

```
type = PTR, class = IN, ttl = 7 hours 47 mins 2 secs, dlen = 23
domain name = playground.sun.com
```

FILES /usr/include/arpa/nameser.h include file for implementation of DNS protocol
 /usr/include/resolv.h include file for the resolver daemon (in.named)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO nslookup(1M), resolver(3RESOLV), attributes(5)

nsupdate(1M)

NAME	nsupdate – update Internet name servers interactively
SYNOPSIS	nsupdate [-k <i>keydir:keyname</i>] [-d] [-v] [<i>filename</i>]
DESCRIPTION	The nsupdate program can be used to update Internet domain name servers that support dynamic update. nsupdate uses the DNS resolver library to pass messages to the DNS server requesting the addition or deletion of DNS resource records (RR's). nsupdate reads input from <i>filename</i> or from standard input.
OPTIONS	nsupdate supports the following options: -d Debug mode. -k Sign updates with Secret Key Transaction Authentication for DNS (TSIG). -v Virtual circuit. Make use of TCP to communicate with the server. The default is UDP.
USAGE	<p>nsupdate reads input records, one per line. Each line contributes a resource record to an update request. All domain names used in a single update request must belong to the same DNS zone. A blank line causes the accumulated records to be formatted into a single update request and transmitted to the zone's authoritative name servers. Additional records may follow, which are formed into additional, but completely independent, update requests. End the input with a blank line in order to transmit the last request.</p> <p>Records take one of two general forms. Prerequisite records specify conditions that must be satisfied before the request will be processed. Update records specify changes to be made to the DNS database. An update request consists of zero or more prerequisites and one or more updates. Each update request is processed atomically. All prerequisites must be satisfied, then all updates will be performed.</p> <p>nsupdate understands the following input record formats:</p> <pre>prereq nxdomain domain-name</pre> <p>This format requires that no RR of any type exist with name <i>domain-name</i>.</p> <pre>prereq yxdomain domain-name</pre> <p>This format requires that at least one RR names <i>domain-name</i> must exist.</p> <pre>prereq nxrrset domain-name [class] type</pre> <p>This format requires that no RR exist of the specified type and <i>domain-name</i>.</p> <pre>prereq yxrrset domain-name [class] type [data ...]</pre>

This format requires that an RR exist of the specified *type* and *domain-name*. If *data* is specified, it must match exactly.

```
update delete domain-name [class] [type [data ...]]
```

This format deletes RR's names *domain-name*. If *type* (and possibly *data*) are specified, only matching records will be deleted.

```
update add domain-name ttl [class] type data ...
```

This format adds a new RR of specified *ttl*, *type* and *data*.

EXAMPLES

EXAMPLE 1 Using nsupdate Interactively To Change an IP Address

The following example shows the interactive use of `nsupdate` to change an IP address. It deletes any existing A records for a domain name and then inserts a new address. Since no prerequisites are specified, the new record will be added even if there are no existing records to delete. A trailing blank line is required to process the request.

```
example$ nsupdate
>update delete test.example.com A
>update add test.example.com 3600 A 10.1.1.1
>
```

EXAMPLE 2 Using nsupdate Interactively to Add a CNAME (Alias)

In the following example, a CNAME (alias) is added to the database only if there are no existing A or CNAME records for the domain name.

```
example$ nsupdate
>prereq nxrrset www.example.com A
>prereq nxrrset www.example.com CNAME
>update add www.example.com 3600 CNAME test.test.com
>
```

EXAMPLE 3 Using nsupdate Interactively With a Key

In the following example, `nsupdate` is signed with the key `mykey`, which is located in the directory `/var/named/keys`.

```
example$ nsupdate -k /var/named/keys:mykey
>update add ftp.example.com 60 A 192.168.5.1
>
```

FILES /etc/resolv.conf Initial domain name and name server addresses.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

DIAGNOSTICS

`Qq send error`

This message typically indicates that authoritative name servers could not be reached.

`Qq failed update packet`

This message typically indicates that the name server has rejected the update. Either the name server does not support dynamic update, or there was an authentication failure.

`Qq res_mkupdate: packet size = size`

If this is the only message sent, it indicates that the update was received and authenticated by the name server. However, the prerequisites may have prevented the update from being performed. Use debug mode (the `-d` option) to examine the status field in the name server's reply and determine if the update was performed.

NAME	ntpd - set the date and time by way of NTP
SYNOPSIS	<code>/usr/sbin/ntpd</code> [-bBdoqsuv] [-a <i>key#</i>] [-e <i>authdelay</i>] [-k <i>keyfile</i>] [-m] [-o <i>version</i>] [-p <i>samples</i>] [-t <i>timeout</i>] [-w] <i>server...</i>
DESCRIPTION	<p>The <code>ntpd</code> utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these.</p> <p>The reliability and precision of <code>ntpd</code> improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more.</p> <p>The <code>ntpd</code> utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling <code>gettimeofday(3C)</code>. If the error is less than 0.5 seconds, by default, it slews the clock's time with the offset, by way of a call to <code>adjtime(2)</code>. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when <code>ntpd</code> is run by <code>cron</code> every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the <code>-b</code> option on the command line.</p> <p>The <code>ntpd</code> utility declines to set the date if an NTP server daemon like <code>xntpd(1M)</code> is running on the same host. It can be run on a regular basis from <code>cron(1M)</code> as an alternative to running a daemon. Doing so once every one to two hours results in precise enough timekeeping to avoid stepping the clock.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a <i>key#</i> Authenticate transactions, using the key number, <i>key#</i>. -b Step the time by calling <code>gettimeofday(3C)</code>. -B Force the time to always be slewed using the <code>adjtime(2)</code> system call, even if the measured offset is greater than +-128 ms. The default is to step the time using <code>settimeofday(3C)</code> if the offset is greater than +-128 ms. If the offset is much greater than +-128 ms in this case, that it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients. -d Display what will be done without actually doing it. Information useful for general debugging is also printed. -e <i>authdelay</i> Specify an authentication processing delay, <i>authdelay</i> in seconds. See <code>xntpd(1M)</code> for details. This number is usually small enough to

ntpd(1M)

- be negligible for purposes of `ntpd`. However, specifying a value may improve timekeeping on very slow CPU's.
- k *keyfile* Read keys from the file *keyfile* instead of the default file, `/etc/ntp.keys`. *keyfile* should be in the format described in `xntpd(1M)`.
 - m Join multicast group specified in *server* and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.
 - o *version* Force the program to poll as a version 1 or version 2 implementation. By default `ntpd` claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.
 - p *samples* Set the number of samples `ntpd` acquires from each server. *samples* can be between 1 and 8 inclusive. The default is 4.
 - q Query only. Do not set the clock.
 - s Log actions by way of the `syslog(3C)` facility rather than to the standard output — a useful option when running the program from `cron(1M)`.
 - t *timeout* Set the time `ntpd` spends, waiting for a response. *timeout* is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.
 - u Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. The `-d` option always uses unprivileged ports.
 - v Be verbose. This option causes `ntpd`'s version identification string to be logged.
 - w Wait until able to synchronize with a server. When the `-w` option is used together with `-m`, `ntpd` waits until able to join the group and synchronize.

FILES `/etc/inet/ntp.keys` Contains the encryption keys used by `ntpd`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

SEE ALSO | cron(1M), xntpd(1M), adjtime(2), gettimeofday(3C),
settimeofday(3C)syslog(3C), attributes(5)

NOTES | The technique of compensating for clock oscillator errors to improve accuracy is
inadequate. However, to further improve accuracy would require the program to save
state from previous runs.

ntpq(1M)

NAME	ntpq – standard Network Time Protocol query program
SYNOPSIS	<code>/usr/sbin/ntpq [-inp] [-c <i>command</i>] [<i>host</i>] [...]</code>
DESCRIPTION	<p>ntpq queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-printed output options available. By sending multiple queries to the server, ntpq can also obtain and print a list of peers in a common format.</p> <p>If one or more request options are included on the command line, ntpq sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, ntpq sends its requests to localhost, if hosts are not included on the command line. If no request options are given, ntpq attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, ntpq defaults to localhost if no other host is specified.</p> <p>ntpq uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances. ntpq makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.</p>
OPTIONS	<p>Command line options are described below. Specifying a command line option other than -i or -n causes the specified query (queries) to be sent, immediately to the indicated host(s). Otherwise, ntpq attempts to read interactive format commands from standard input.</p> <ul style="list-style-type: none">-c Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.-i Operate in interactive mode; write prompts to standard output and read commands from standard input.-n Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.-p Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.
USAGE	<p>Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>', followed by a file name, to the command line.</p>

**Interactive
Commands**

A number of interactive format commands are executed entirely within the `ntpq` program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, `ntpq` prompts for these commands. The interactive commands are described below:

? [*command_keyword*]

A '?' by itself prints a list of all the command keywords known to the current version of `ntpq`. A '?' followed by a command keyword prints function and usage information about the command.

timeout *milliseconds*

Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since `ntpq` retries each query once after a time out, the total waiting time for a time out is twice the time out value that is set.

delay *milliseconds*

Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.

host *hostname*

Set the name of the host to which future queries are to be sent. *Hostname* may be either a host name or a numeric address.

keyid #

Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.

passwd

Prompts the user to type in a password which will be used to authenticate configuration requests. If an authenticating key has been specified (see `keyid` above), this password must correspond to this key. `ntpq` does not echo the password as it is typed.

hostnames *yes* | *no*

If "yes" is specified, host names are printed in information displays. If "no" is given, numeric addresses are printed instead. The default is "yes" unless modified using the command line `-n` switch.

raw

Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non-ASCII data into printable form.

cooked

Causes output from query commands to be "cooked". The values of variables recognized by the server are reformatted, so that they can be more easily read.

ntpq(1M)

Variables which ntpq thinks should have a decodable value, but do not, are marked with a trailing '?'.

`ntpversion [1 | 2 | 3]`

Sets the NTP version number which ntpq claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

`authenticate [yes | no]`

The command `authenticate yes` instructs ntpq to send authentication with all requests it makes. Normally ntpq does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display. `addvars variable_name[=value] [. . .]` `rmvars variable_name [. . .]` `clearvars`

The data carried by NTP mode 6 messages consists of a list of items of the form

`variable_name=value` where the "`=value`" is ignored, and can be omitted, in requests to the server to read variables. ntpq maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the `readlist` and `writelst` commands described below. The `addvars` command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The `rmvars` command can be used to remove individual variables from the list; the `clearlist` command removes all variables from the list.

`debug [more | less | off]`

Turns internal query program debugging on and off.

`quit`

Exit ntpq.

Control Message Commands

Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.

Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the `peers` `mreadlist` and `mreadvar` commands. The `peers` command sends a preprogrammed series of messages to obtain the data it needs. The `mreadlist` and `mreadvar` commands, iterate over a range of associations.

Control message commands are described below:

associations

Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the `associations` command is cached internally in `ntpq`. The index is then of use when dealing with “dumb” servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, *&index*. Here *index* is taken from the previous list.

lassociations

Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining *state*. This command differs from the `associations` command only for servers which retain *state* for out-of-spec client associations. Such associations are normally omitted from the display when the `associations` command is used, but are included in the output of `lassociations`.

passociations

Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the `associations` command except that it displays the internally stored data rather than making a new query.

lpassociations

Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from `passociations` only when dealing with servers which retain *state* for out-of-spec client associations.

pstatus *assocID*

Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

readvar [*assoc*] [*variable_name*[=*value*] [, . . .]]

Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

rv [*assocID*] [*variable_name*[=*value*] [, . . .]]

An easy-to-type short form for the `readvar` command.

ntpq(1M)

`writevar assocID variable_name=value [, . . .]`
Like the `readvar` request, except the specified variables are written instead of read.

`readlist [assocID]`
Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

`r1 [assocID]`
An easy-to-type short form of the `readlist` command.

`writelist [assocID]`
Like the `readlist` request, except the internal list variables are written instead of read.

`mreadvar assocID assocID [variable_name[=value] [, . . .]]`
Like the `readvar` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mr1 assocID assocID [variable_name[=value] [, . . .]]`
An easy-to-type short form of the `mreadvar` command.

`mreadlist assocID assocID`
Like the `readlist` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mr1 assocID assocID`
An easy-to-type short form of the `mreadlist` command.

`clockvar [assocID] [variable_name[=value] [, . . .]]`
Requests that a list of the server's clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the "system clock". This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

`cv [assocID] [variable_name[=value] [, . . .]]`
An easy-to-type short form of the `clockvar` command.

`peers`
Obtains a list of in-spec peers of the server, along with a summary of each peer's state. Summary information includes:

- The address of the remote peer

- The reference ID (0.0.0.0 if the ref ID is unknown)
- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in milliseconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

SPACE	Discarded due to high stratum and/or failed sanity checks.
x	Designated falsticker by the intersection algorithm.
.	Culled from the end of the candidate list.
-	Discarded by the clustering algorithm.
+	Included in the final selection set.
#	Selected for synchronization; but distance exceeds maximum.
*	Selected for synchronization.
o	Selected for synchronization, pps signal in use.

Since the `peers` command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the host field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, `REFCLK(implementation number, parameter)`. On “hostnames no” only IP-addresses will be displayed.

lpeers

Like `peers`, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

opeers

An old form of the `peers` command with the reference ID replaced by the local interface address.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ntpq(1M)

SEE ALSO | attributes(5)

BUGS The `peers` command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command.

The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.

NAME	ntptrace – trace a chain of NTP hosts back to their master time source				
SYNOPSIS	<code>/usr/sbin/ntptrace [-vdn] [-r <i>retries</i>] [-t <i>timeout</i>] [<i>server</i>]</code>				
DESCRIPTION	ntptrace determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with <i>localhost</i> .				
OPTIONS	<p><code>-d</code> Turns on some debugging output.</p> <p><code>-n</code> Turns off the printing of host names; instead, host IP addresses are given. This may be necessary if a nameserver is down.</p> <p><code>-r <i>retries</i></code> Sets the number of retransmission attempts for each host.</p> <p><code>-t <i>timeout</i></code> Sets the retransmission timeout (in seconds); default = 2.</p> <p><code>-v</code> Prints verbose information about the NTP servers.</p>				
EXAMPLES	<p>EXAMPLE 1 A sample output of ntptrace.</p> <p>Here is an example of the output from ntptrace:</p> <pre>% ntptrace localhost: stratum 4, offset 0.0019529, synch distance 0.144135 server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784 usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'</pre> <p>On each line, the fields are (left to right):</p> <ul style="list-style-type: none"> ■ The server's host name ■ The server's stratum ■ The time offset between that server and the local host (as measured by ntptrace; this is why it is not always zero for <i>localhost</i>) ■ The host's synchronization distance ■ The reference clock ID (only for stratum-1 servers) <p>All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.</p>

obpsym(1M)

NAME	obpsym – Kernel Symbolic Debugging for OpenBoot Firmware
SYNOPSIS	modload -p misc/obpsym
DESCRIPTION	<p>obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric <i>addresses</i> to kernel symbol names for display purposes, and to convert kernel symbol names to numeric <i>literals</i> allowing symbolic names to be used as input arguments to user interface commands.</p> <p>Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands <code>ctrace</code> and <code>dis</code> typically display symbolic names and offsets in the form <i>modname:symbolname + offset</i>. User interface Commands such as <code>dis</code> can be given a kernel symbolic name such as <code>ufs:ufs_mount</code> instead of a numeric address.</p> <p>Placing the command</p> <pre>forceload: misc/obpsym</pre> <p>into the <code>system(4)</code> file forces the kernel module <code>misc/obpsym</code> to be loaded and activates the kernel callbacks during the kernel startup sequence.</p> <p>obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's <code>ctrace</code> command to display symbolic names in the stack backtrace after a watchdog reset.</p>
Kernel Symbolic Name Syntax	<p>The syntax for a kernel symbolic name is:</p> <pre>[<i>module-name</i> :] <i>symbol-name</i></pre> <p>Where <i>module-name</i> is the name of the kernel module that the symbol <i>symbol-name</i> appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name <code>unix</code> is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided.</p> <p>Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal <i>vocabulary</i> before checking if the word is a <i>literal</i>. Thus, kernel symbols, such as <code>reset</code> may be given as <code>unix:reset</code> to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.</p>
FILES	<pre>/etc/system system configuration information file</pre>

OpenBoot 3.x Command Reference Manual

WARNINGS Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

NOTES *platform-name* can be found using the `-i` option of `uname(1)`

`obpsym` is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the `obpsym` symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, `obpsym` may complain that it requires that "you must use `ramforth` to use this module".

See the *OpenBoot 3.x Command Reference Manual* for details on how to use the `ramforth` command, how to place the command into `nvramrc`, and how to set `use-nvramrc?` to `true`. On systems with version 1.x OpenBoot firmware, `nvramrc` doesn't exist, and the `ramforth` command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

ocfserv(1M)

NAME | ocfserv – OCF server

SYNOPSIS | **ocfserv** start
| **ocfserv** stop

DESCRIPTION | The OCF server, *ocfserv*, is a per-host daemon that acts as the central point of communications with all smartcards connected to the host. Any application needing to use a smartcard communicates with the smartcard through this server, which is responsible for handling all traffic to the smartcards. All APIs exposed by this project are internally implemented to communicate with the OCF server. Applications communicate with the OCF server using a socket-based protocol.

| At startup time, the server reads the properties file to determine the terminals and cards currently registered.

EXIT STATUS | The following exit values are returned:
| 0 Successful completion.
| >0 An error occurred.

USAGE | Root privileges are required to execute this utility.

FILES | /etc/smartcard/opencard.properties
| file where server stores properties

ATTRIBUTES | See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWocfr

SEE ALSO | *smartcard(1M)*, *attributes(5)*, *smartcard(5)*

NAME parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries

SYNOPSIS <cdrom>/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc
 <cdrom>/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc

DESCRIPTION This script parses the clustertoc file before the suninstall(1M) process is run. parse_dynamic_clustertoc is called by a modified sysconfig script on the install CD. When parse_dynamic_clustertoc runs, it reads the clustertoc and when it encounters SUNW_CSRMBRIFF lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the SUNW_CSRMBRIFF = (<test> <test_arg>) <cluster> line is converted to SUNW_CSRMEMBER = <cluster>.

EXAMPLES **EXAMPLE 1** A simple external test to check for a SX Framebuffer.

The following is an example of a simple external test to check for a SX Framebuffer. The entry in the clustertoc file is shown and following that is the script that must be placed in the install.d/dynamic_test directory.

```
SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx
#!/bin/sh
#
# Likewise, this file is expected to live under $(TESTDIR).
#
case "$1"
in
    sx)    prtconf -p | grep 'SUNW,sx' 1> /dev/null;;
esac
```

FILES <cdrom>/Solaris_2.x/locale/C/.clustertoc.dynamic
 dynamic version of the clustertoc file

<cdrom>/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test
 directory that contains any additional tests

<cdrom>/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test
 directory that contains any additional tests

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

passmgmt(1M)

NAME	passmgmt – password files management
SYNOPSIS	passmgmt -a <i>options name</i> passmgmt -m <i>options name</i> passmgmt -d <i>name</i>
DESCRIPTION	<p>The passmgmt command updates information in the password files. This command works with both <code>/etc/passwd</code> and <code>/etc/shadow</code>.</p> <p>passmgmt -a adds an entry for user <i>name</i> to the password files. This command does not create any directory for the new user and the new login remains locked (with the string <code>*LK*</code> in the password field) until the <code>passwd(1)</code> command is executed to set the password.</p> <p>passmgmt -m modifies the entry for user <i>name</i> in the password files. The name field in the <code>/etc/shadow</code> entry and all the fields (except the password field) in the <code>/etc/passwd</code> entry can be modified by this command. Only fields entered on the command line will be modified.</p> <p>passmgmt -d deletes the entry for user <i>name</i> from the password files. It will not remove any files that the user owns on the system; they must be removed manually.</p> <p>passmgmt can be used only by the super-user.</p>
OPTIONS	<p>-c <i>comment</i> A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field.</p> <p>-h <i>homedir</i> Home directory of <i>name</i>. It is limited to a maximum of 256 characters and defaults to <code>/usr/name</code>.</p> <p>-u <i>uid</i> UID of the <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. It defaults to the next available UID greater than 99. Without the <code>-o</code> option, it enforces the uniqueness of a UID.</p> <p>-o This option allows a UID to be non-unique. It is used only with the <code>-u</code> option.</p> <p>-g <i>gid</i> GID of <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. The default is 1.</p> <p>-s <i>shell</i> Login shell for <i>name</i>. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of <i>shell</i> is 256 characters. The default is for this field to be empty and to be interpreted as <code>/usr/bin/sh</code>.</p> <p>-l <i>logname</i> This option changes the <i>name</i> to <i>logname</i>. It is used only with the <code>-m</code> option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.</p>
FILES	<code>/etc/passwd</code> <code>/etc/shadow</code>

/etc/passwd
/etc/shadow

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `passwd(1)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

EXIT STATUS The `passmgmt` command exits with one of the following values:

- 0 Success.
- 1 Permission denied.
- 2 Invalid command syntax. Usage message of the `passmgmt` command is displayed.
- 3 Invalid argument provided to option.
- 4 UID in use.
- 5 Inconsistent password files (for example, *name* is in the `/etc/passwd` file and not in the `/etc/shadow` file, or vice versa).
- 6 Unexpected failure. Password files unchanged.
- 7 Unexpected failure. Password file(s) missing.
- 8 Password file(s) busy. Try again later.
- 9 *name* does not exist (if `-m` or `-d` is specified), already exists (if `-a` is specified), or `logname` already exists (if `-m -l` is specified).

NOTES Do not use a colon (:) or RETURN as part of an argument. It is interpreted as a field separator in the password file. The `passmgmt` command will be removed in a future release. Its functionality has been replaced and enhanced by `useradd`, `userdel`, and `usermod`. These commands are currently available.

This command only modifies password definitions in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `passmgmt` cannot change information supplied by the network nameservice.

patchadd(1M)

NAME	patchadd – apply a patch package to a Solaris 2 or Solaris 7 system
SYNOPSIS	patchadd [-d] [-u] [-B <i>backout_dir</i>] [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] <i>patch</i> patchadd [-d] [-u] [-B <i>backout_dir</i>] [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] -M <i>patch_dir</i> <i>patch_id...</i> <i>patch_dirpatch_list</i> patchadd [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] -p
DESCRIPTION	<p>patchadd applies a patch package to a Solaris 2 or compatible version system. This patch installation utility can not be used to apply Solaris 1 patches. patchadd must be run as root.</p> <p>There are three forms of the patchadd command.</p> <p>The first form of patchadd installs <i>one</i> patch to a system, client, service, or the mini root of a Net Install Image.</p> <p>The second form of patchadd installs <i>more than one</i> patch to a system, client, service, or the mini root of a Net Install Image.</p> <p>The third form of patchadd <i>displays</i> installed patches on the client, service, or the mini root of a Net Install Image.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-d Does not back up the files to be patched. <i>The patch cannot be removed.</i>-p Displays a list of the patches currently applied.-u Installs unconditionally, turns off file validation. Applies the patch even if some of the files to be patched have been modified since their original installation.-B <i>backout_dir</i> Saves backout data to a directory other than the package database. Specify <i>backout_dir</i> as an absolute path name.-C <i>net_install_image</i> Patches the files located on the mini root on a Net Install Image created by <i>setup_install_server</i>. Specify <i>net_install_image</i> as the absolute path name to a Solaris 2.6 or compatible version boot directory. See EXAMPLES.-M <i>patch_dir patch_id . . . patch_dir patch_list</i> Specifies the patches to be installed. Specify patches to the -M option in one of the following ways:<ol style="list-style-type: none">1. By directory location <i>and</i> patch number.

To use the directory location and patch number, specify *patch_dir* as the absolute path name of the directory that contains spooled patches. Specify *patch_id* as the patch number of a given patch. Specifying multiple *patch_id*'s is recommended.

2. By directory location *and* the name of a file containing a patch list.

To use the directory location and a file containing a patch list, specify *patch_dir* as the absolute path name of the directory containing the file with a list of patches to be installed. Specify *patch_list* as the name of the file containing the patches to be installed.

-R *client_root_path*

Locates all patch files generated by patchadd under the directory *client_root_path*. *client_root_path* is the directory that contains the bootable root of a client from the server's perspective. Specify *client_root_path* as the absolute path name to the beginning of the directory tree under which all patch files generated by patchadd are to be located. -R cannot be specified with the -S option. See NOTES.

-S *service*

Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option. See NOTES.

OPERANDS The following operands are supported:

<i>patch</i>	The absolute path name to <i>patch_id</i> . /var/sadm/spool/patch/104945-02 is an example of a patch.
<i>patch_dir</i>	The absolute path name to the directory that contains all the spooled patches. /var/sadm/spool/patch is an example of a <i>patch_dir</i> .
<i>patch_id</i>	The patch number of a given patch. 104945-02 is an example of a <i>patch_id</i> .
<i>patch_list</i>	The name of a file that contains a list of patches to install. <i>patch_list</i> files contain one <i>patch_id</i> on each line.

EXAMPLES **EXAMPLE 1** Installing a patch to a standalone machine.

The examples in this section are all relative to the /usr/sbin directory.

The following example installs a patch to a standalone machine:

```
example# patchadd /var/spool/patch/104945-02
```

patchadd(1M)

EXAMPLE 1 Installing a patch to a standalone machine. *(Continued)*

EXAMPLE 2 Installing a patch to a client from the server's console.

The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1 /var/spool/patch/104945-02
```

EXAMPLE 3 Installing a patch to a service from the server's console.

The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_2.3 /var/spool/patch/104945-02
```

EXAMPLE 4 Installing multiple patches in a single patchadd invocation.

The following example installs multiple patches in a single patchadd invocation:

```
example# patchadd -M /var/spool/patch 104945-02 104946-02 102345-02
```

EXAMPLE 5 Installing multiple patches specifying a file with the list of patches to install.

The following example installs multiple patches specifying a file with the list of patches to install:

```
example# patchadd -M /var/spool/patch patchlist
```

EXAMPLE 6 Installing multiple patches to a client and saves the backout data to a directory other than the default.

The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/spool/patch -R /export/root/client1  
-B /export/backoutrepository 104945-02 104946-02 102345-02
```

EXAMPLE 7 Installing a patch to a Solaris 2.6 or compatible version Net Install Image.

The following example installs a patch to a Solaris 2.6 or compatible version Net Install Image:

```
example# patchadd -C /export/Solaris_2.6/Tools/Boot  
/var/spool/patch/104945-02
```

EXAMPLE 8 Displaying the patches installed on a client.

The following example displays the patches installed on a client:

```
example# patchadd -R /export/root/client1 -p
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

DIAGNOSTICS The following messages may help in determining some of the most common problems associated with installing a patch.

Patch Installation errors

Message

The prepatch script exited with return code *retcode*.
patchadd is terminating.

Explanation and Recommended Action

The prepatch script supplied with the patch exited with a return code other than 0. Run a script trace of the prepatch script and find out why the prepatch had a bad return code. Add the `-x` option to the first line of the prepatch script to fix the problem and run patchadd again.

Message

The postpatch script exited with return code *retcode*.
Backing out patch.

Explanation and Recommended Action

The postpatch script provided with the patch exited with an error code other than 0. This script is mostly used to cleanup files (that is, when a package is known to have ownership or permission problems) attributes that don't correspond to the patch package's objects. After the user has noted all validation errors and taken the appropriate action for each one, the user should re-run patchadd using the `-u` (unconditional) option. This time, the patch installation will ignore validation errors and install the patch anyway.

Message

Insufficient space in `/var/sadm/patch` to save old files.
(For 2.4 systems and previous)

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/patch` directory to save old files. The user has three options for handling this problem: Use the `-B` option while invoking patchadd. This option will direct patchadd to: save the backout data to the user specified file system, generate additional disk space by deleting unneeded files, or override the saving of the old files by using the `-d` (do not save) option when running patchadd.

patchadd(1M)

If the user elects not to save the old versions of the files to be patched, `patchrm` cannot be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for `patch` *patch_id*:

```
cd /var/sadm/patch/patch_id
rm -r save/*
rm .oldfilessaved
```

After these commands have been executed, `patch` *patch_id* can no longer be backed out.

Message

```
Insufficient space in /var/sadm/pkg/PKG/save to save old files.
(For 2.5 systems and later)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/pkg/PKG/save` directory to save old files. The user has three options for handling this problem: (1) Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to save the backout data to the user specified file system. (See above synopsis) (2) Generate additional disk space by deleting unneeded files, or (3) override the saving of the old files by using the `-d` (do not save) option when running `patchadd`.

However if the user elects not to save the old versions of the files to be patched, `patchrm` cannot be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for `patch` *patch_id*:

```
cd /var/sadm/pkg/pkgabbrev/save
rm -r patch_id
```

After these commands have been executed, `patch` *patch_id* can no longer be backed out.

Message

```
Save of old files failed.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

Before applying the patch, the patch installation script uses `cpio` to save the old versions of the files to be patched. This error message means that the `cpio` failed. The output of the `cpio` would have been preceded this message. The user should take the appropriate action to correct the `cpio` failure. A common reason for failure will be insufficient disk space to save the old versions of the files. The user has two options for handling insufficient disk space: (1) generate additional disk space by deleting unneeded files, or (2) override the saving of the old files by using the `-d` option when running `patchadd`. However if the user elects not

to save the old versions of the files to be patched, the patch *cannot* be backed out.

Message

```
Pkgadd of pkgname package failed with error code code.
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. patchadd will backout the patch to leave the system in its pre-patched state. See the log file for the reason for failure. Correct the problem and re-apply the patch.

Message

```
Pkgadd of pkgname package failed with error code code.
Will not backout patch_id patch re-installation.
Warning: The system may be in an unstable state!
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. patchadd will *not* backout the patch. You may manually backout the patch using patchrm, then re-apply the entire patch. Look in the log file for the reason pkgadd failed. Correct the problem and re-apply the patch.

Message

```
patchadd is unable to find the INST_RELEASE file. This file
must be present for patchadd to function correctly.
```

Explanation and Recommended Action

The INST_RELEASE file is missing from the system. This file is created during either initial installation or during an update.

Message

```
A previous installation of patch patch_id was invoked
that saved files that were to be patched. Since files
were saved, you must run this instance of patchadd
without the -d option.
```

Explanation and Recommended Action

If a patch was previously installed without using the -d option, then the re-installation attempt must also be invoked without the -d option. Execute patchadd without the -d option.

Message

```
A previous installation of patch patch_id was invoked
with the -d option. (i.e. Do not save files that would
be patched) Therefore, this invocation of patchadd
must also be run with the -d option.
```

patchadd(1M)

Diagnostic Reference

Explanation and Recommended Action

If a patch was previously installed using the `-d` option, then the re-installation attempt must also be invoked with the `-d` option. Execute `patchadd` with the `-d` option.

The patch installation messages listed below are not necessarily considered errors as indicated in the explanations given. These messages are, however, recorded in the patch installation log for diagnostic reference.

Message

```
Package not patched:
PKG=SUNxxxx
Original package not installed
```

Explanation and Recommended Action

One of the components of the patch would have patched a package that is not installed on your system. This is not necessarily an error. A patch may fix a related bug for several packages.

For example, suppose a patch fixes a bug in both the `online-backup` and `fddi` packages. If you had `online-backup` installed but didn't have `fddi` installed, you would get the message :

```
Package not patched:
PKG=SUNWbf
Original package not installed
```

This message only indicates an error if you thought the package was installed on your system. If this is the case, take the necessary action to install the package, backout the patch (if it installed other packages) and re-install the patch.

Message

```
Package not patched:
PKG=SUNxxx
ARCH=xxxxxxx
VERSION=xxxxxxx
Architecture mismatch
```

Explanation and Recommended Action

One of the components of the patch would have patched a package for an architecture different from your system. This is not necessarily an error. Any patch to one of the architecture specific packages may contain one element for each of the possible architectures. For example, Assume you are running on a `sun4m`. If you were to install a patch to package `SUNWcar`, you would see the following (or similar) messages:

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4c
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4d
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4e
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

The only time these messages indicate an error condition is if `patchadd` does not correctly recognize your architecture.

Message

```
Package not patched:
PKG=SUNxxxx
ARCH=xxxx
VERSION=xxxxxxxx
Version mismatch
```

Explanation and Recommended Action

The version of software to which the patch is applied is not installed on your system. For example, if you were running Solaris 5.5, and you tried to install a patch against Solaris 5.6, you would see the following (or similar) message:

```
Package not patched:
PKG=SUNWcsu
ARCH=sparc
VERSION=10.0.2
Version mismatch
```

This message does not necessarily indicate an error. If the version mismatch was for a package you needed patched, either get the correct patch version or install the correct package version. Then backout the patch (if necessary) and re-apply.

Message

```
Re-installing Patch.
```

Explanation and Recommended Action

The patch has already been applied, but there is at least one package in the patch that could be added. For example, if you applied a patch that had both Openwindows and Answerbook components, but your system did not have Answerbook installed, the Answerbook parts of the patch would not have been applied. If, at a later time, you `pkgadd` Answerbook, you could re-apply the patch, and the Answerbook components of the patch would be applied to the system.

patchadd(1M)

Message

```
patchadd Interrupted.  
patchadd is terminating.
```

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c).
patchadd will clean up its working files and exit.

Message

```
patchadd Interrupted.  
Backing out Patch...
```

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c).
patchadd will clean up its working files, backout the patch, and exit.

SEE ALSO cpio(1), pkginfo(1), patchrm(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M),
showrev(1M), attributes(5)

NOTES To successfully install a patch to a client or server, patchadd must be issued twice, once with the -R option and once with the -S option. This guarantees that the patch is installed to both the /usr and root partitions. This is necessary if there are both /usr and root packages in the patch.

pkgadd is invoked by patchadd and executes the installation scripts in the *pkg/install* directory. The checkinstall script is executed with its ownership set to user install, if there is no user install then pkgadd executes the checkinstall script as nobody. The SVR4 ABI states that the checkinstall shall only be used as an information gathering script. If the permissions for the checkinstall script are changed to something other than the initial settings, pkgadd may not be able to open the file for reading, thus causing the patch installation to abort with the following error:

```
pkgadd: ERROR: checkinstall script did not complete successfully.
```

The permission for the checkinstall script should not be changed. Contents of log file for a successful installation: patchadd redirects pkgadd's output to the patch installation log file. For a successful installation, pkgadd will produce the following message that gets inserted into the log file:

```
This appears to be an attempt to install the same architecture  
and version of a package which is already installed. This  
installation will attempt to overwrite this package.
```

This message does not indicate a failure, it represents the correct behavior by pkgadd when a patch installs correctly.

On client server machines the patch package is *not* applied to existing clients or to the client root template space. Therefore, when appropriate, *all client machines will need the patch applied directly using this same patchadd method on the client.* See instructions above for applying patches to a client. A bug affecting a package utility (for example,

pkgadd, pkgrm, pkgchk) could affect the reliability of patchadd or patchrm which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

patchrm(1M)

NAME	patchrm – remove a Solaris 2 or Solaris 7 patch package and restore previously saved files
SYNOPSIS	patchrm [-f] [-B <i>backout_dir</i>] [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] <i>patch_id</i>
DESCRIPTION	<i>patchrm</i> removes a patch package and restores previously saved files to a Solaris 2 or Solaris 7 system. <i>patchrm</i> cannot be used with Solaris 1 patches. <i>patchrm</i> must be run as root.
OPTIONS	The following options are supported: -f Forces the patch removal regardless of whether the patch was superseded by another patch. -B <i>backout_dir</i> Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the <i>patchadd</i> command at installation time, has been moved. Specify <i>backout_dir</i> as an absolute path name. -C <i>net_install_image</i> Removes the patched files located on the mini root on a Net Install Image created by <i>setup_install_server</i> . Specify <i>net_install_image</i> as the absolute path name to a Solaris 2.6 or compatible version boot directory. See EXAMPLES . -R <i>client_root_path</i> Locates all patch files generated by <i>patchrm</i> under the directory <i>client_root_path</i> . <i>client_root_path</i> is the directory that contains the bootable root of a client from the server's perspective. Specify <i>client_root_path</i> as the absolute path name to the beginning of the directory tree under which all patch files generated from <i>patchrm</i> will be located. -R cannot be specified with the -S option. -S <i>service</i> Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option..
OPERANDS	The following operands are supported: <i>patch_id</i> The patch number of a given patch. 104945-02 is an example of a <i>patch_id</i> .

EXAMPLES **EXAMPLE 1** Removing a patch from a standalone system.

The examples in this section assume that patch 104945-02 has been installed to the system prior to removal. All of the examples are relative to the `/usr/sbin` directory.

The following example removes a patch from a standalone system:

```
example# patchrm 104945-02
```

EXAMPLE 2 Removing a patch from a client's system from the server's console.

The following example removes a patch from a client's system from the server's console:

```
example# patchrm -R /export/root/client1 104945-02
```

EXAMPLE 3 Removing a patch from a server's service area.

The following example removes a patch from a server's service area:

```
example# patchrm -S Solaris_2.3 104945-02
```

EXAMPLE 4 Removing a patch from a Net Install Image.

The following example removes a patch from a Net Install Image:

```
example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

DIAGNOSTICS The following messages may help in determining some of the most common problems associated with backing out a patch.

Message

```
prebackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The prebackout script supplied with the patch exited with a return code other than 0. Generate a script trace of the prebackout script to determine why the

patchrm(1M)

prebackout script failed. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
postbackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The postbackout script supplied with the patch exited with a return code other than 0. Look at the postbackout script to determine why it failed. Add the `-x` option to the first line of the prepatch script to fix the problem, and, if necessary, *re-execute the postbackout script only*.

Message

```
Only one service may be defined.
```

Explanation and Recommended Action

You have attempted to specify more than one service from which to backout a patch. Different services must have their patches backed out with different invocations of `patchrm`.

Message

```
The -S and -R arguments are mutually exclusive.
```

Explanation and Recommended Action

You have specified both a non-native service and a *client_root_path* from which to backout a patch. These two arguments are mutually exclusive. If backing out a patch from a non-native `usr` partition, the `-S` option should be used. If backing out a patch from a client's root partition (either native or non-native), the `-R` option should be used.

Message

```
The service service cannot be found on this system
```

Explanation and Recommended Action

You have specified a non-native service from which to backout a patch, but the specified service is not installed on your system. Correctly specify the service when backing out the patch.

Message

```
Only one client_root_path may be defined.
```

Explanation and Recommended Action

You have specified more than one *client_root_path* using the `-R` option. The `-R` option may be used only once per invocation of `patchrm`.

Message

```
The dir directory cannot be found on this system.
```

Explanation and Recommended Action

You have specified a directory using the `-R` option which is either not mounted, or does not exist on your system. Verify the directory name and re-backout the patch.

Message

```
Patch patch_id has not been successfully installed to this system.
```

Explanation and Recommended Action

You have attempted to backout a patch that is not installed on this system. If you must restore previous versions of patched files, you may have to restore the original files from the initial installation CD.

Message

```
Patch patch_id has not been successfully applied to this system.  
Will remove directory dir.
```

Explanation and Recommended Action

You have attempted to back out a patch that is not applied to this system. While the patch has not been applied, a residual `/var/sadm/patch/patch_id` (perhaps from an unsuccessful `patchadd`) directory still exists. The patch cannot be backed out. If you must restore old versions of the patched files, you may have to restore them from the initial installation CD.

Message

```
This patch was obsoleted by patch patch_id.  
Patches must be backed out in the reverse order in  
which they were installed. Patch backout aborted.
```

Explanation and Recommended Action

You are attempting to backout patches out of order. Patches should never be backed-out out of sequence. This could undermine the integrity of the more current patch.

Message

```
Patch patch_id is required to be installed by an already installed patch_id.  
It cannot be backed out until the required patch is backed out first.
```

Explanation and Recommended Action

Backout the patch that is required to be installed then backout the desired patch.

Message

```
The installation of patch patch_id was interrupted.
```

Explanation and Recommended Action

A previous installation was interrupted. The interrupted patch needs to be installed before backing out the desired patch.

patchrm(1M)

Message

Patch *patch_id* was installed without backing up the original files. It cannot be backed out.

Explanation and Recommended Action

Either the `-d` option of `patchadd` was set when the patch was applied, or the save area of the patch was deleted to regain space. As a result, the original files are not saved and `patchrm` cannot be used. The original files can only be recovered from the original installation CD.

Message

`pkgadd` of *pkgname* package failed return code *code*.
See `/var/sadm/patch/patch_id/log` for reason for failure.

Explanation and Recommended Action

The installation of one of patch packages failed. See the log file for the reason for failure. Correct the problem and run the backout script again.

Message

Restore of old files failed.

Explanation and Recommended Action

The backout script uses the `cpio` command to restore the previous versions of the files that were patched. The output of the `cpio` command should have preceded this message. The user should take the appropriate action to correct the `cpio` failure. This is for Solaris 2.4 or previous versions.

SEE ALSO `cpio(1)`, `pkginfo(1)`, `patchadd(1M)`, `pkgadd(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `showrev(1M)`, `attributes(5)`

NOTES On client server machines the patch package is *not* removed from existing clients or from client root template space. Therefore, when appropriate, *all client machines will need the patch removed directly using this same patchrm method on the client*. A bug affecting a package utility (for example, `pkgadd`, `pkgrm`, `pkgchk`) could affect the reliability of `patchadd` or `patchrm` which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

pbind(1M)

NAME	pbind – control and query bindings of processes to processors						
SYNOPSIS	pbind -b <i>processor_id</i> <i>pid...</i> pbind -u <i>pid...</i> pbind [-q] [<i>pid...</i>]						
DESCRIPTION	<p>pbind controls and queries bindings of processes to processors. pbind binds all the LWPs (lightweight processes) of a process to a processor, or removes or displays the bindings.</p> <p>When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free execute other LWPs as well.</p> <p>Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.</p> <p>Superusers may bind or unbind any process, and other users can use pbind to bind or unbind any process for which the user has permission to signal, that is, any process that has the same effective user ID as the user.</p>						
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-b <i>processor_id</i></td><td>Binds all the LWPs of the specified processes to the processor <i>processor_id</i>. Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).</td></tr><tr><td>-q</td><td>Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.</td></tr><tr><td>-u</td><td>Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.</td></tr></table>	-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).	-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.	-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.
-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).						
-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.						
-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.						
OPERANDS	<p>The following operands are supported:</p> <table><tr><td><i>pid</i></td><td>The process ID of the process to be controlled or queried.</td></tr></table>	<i>pid</i>	The process ID of the process to be controlled or queried.				
<i>pid</i>	The process ID of the process to be controlled or queried.						
EXAMPLES	EXAMPLE 1						
Binding processes	<p>The following example binds processes 204 and 223 to processor 2.</p> <pre>example% pbind -b 2 204 223</pre>						

Unbinding a process

This command displays the following output:

```
process id 204: was 2, now 2
process id 223: was 3, now 2
```

Querying Bindings

The following example unbinds process 204.

```
example% pbind -u 204
```

The following example demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
```

This command displays the following output:

```
process id 1: 0
process id 149: 3
process id 101: not bound
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

SEE ALSO

`psradm(1M)`, `psrinfo(1M)`, `psrset(1M)`, `processor_bind(2)`, `processor_info(2)`, `sysconf(3C)`, `attributes(5)`

DIAGNOSTICS

- `pbind: cannot query pid 31: No such process`
The process specified did not exist or has exited.
- `pbind: cannot bind pid 31: Not owner`
The user does not have permission to bind the process.
- `pbind: cannot bind pid 31: Invalid argument`
The specified processor is not on-line.

pcmcia(1M)

NAME pcmciad – PCMCIA user daemon
SYNOPSIS /usr/lib/pcmcia
DESCRIPTION The PCMCIA user daemon provides user-level services for the PCMCIA nexus driver and PCMCIA card client drivers. There are no user-configurable options for this daemon.
ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcmcu

SEE ALSO pcmcia(4), attributes(5)
DIAGNOSTICS pcmciad: can't open /dev/pem: No such file or directory
The user daemon could not communicate with the PCMCIA event management driver.

NAME	pfinstall – tests installation profiles
SYNOPSIS	<code>/usr/sbin/install.d/pfinstall -D -d <i>disk_config</i> [-c <i>CDpath</i>] <i>profile</i></code>
DESCRIPTION	<p>After you create a profile, you can use the <code>pfinstall</code> command to test the profile and see if it does what you want before using it to install or upgrade a system. <code>pfinstall</code> enables you to test a profile against:</p> <ul style="list-style-type: none"> ■ The system’s disk configuration where <code>pfinstall</code> is being run. ■ Other disks by using a disk configuration file that represents a structure of a disk. See NOTES on how to create a disk configuration file. <p>To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.6, you have to run the <code>pfinstall</code> command on a system running Solaris 2.6.</p> <p>So, on a system running Solaris 2.6, you can test Solaris 2.6 initial installation profiles. However, if you want to test a Solaris 2.6 upgrade profile on a system running a previous version of Solaris, or if you don’t have a Solaris 2.6 system installed yet to test Solaris 2.6 initial installation profiles, you have to boot a system from a Solaris 2.6 CD image and temporarily create a Solaris 2.6 install environment. Then, you can run <code>pfinstall</code> in the Solaris 2.6 install environment to test your profiles.</p> <p>To create a temporary Solaris 2.6 install environment, boot a system from a Solaris 2.6 CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the <code>pfinstall</code> command.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-D</code> <code>pfinstall</code> uses the system’s disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).</p> <p><code>-d <i>disk_config</i></code> <code>pfinstall</code> uses a disk configuration file, <i>disk_config</i>, to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system’s disk configuration (<code>-D</code> option).</p> <p><code>-c <i>CDpath</i></code> The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code>. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code>.)</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>profile</i> The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.</p>

pfinstall(1M)

EXAMPLES

EXAMPLE 1 Testing an upgrade profile.

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from a Solaris 2.6 image (just as you would to install). The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.
After the Solaris Interactive Installation program exits, a shell prompt is displayed.
5. Create a temporary mount point:

```
example# mkdir /tmp/mnt
```

6. Mount the directory that contains the profile(s) you want to test.

If you want to mount a remote NFS file system (for systems on the network), enter:

```
mount -F nfs server_name:path /tmp/mnt
```

If you want to mount a UFS-formatted diskette, enter:

```
mount -F ufs /dev/diskette /tmp/mnt
```

If you want to mount a PCFS-formatted diskette, enter:

```
mount -F pcfs /dev/diskette /tmp/mnt
```

7. Change directory to `/tmp/mnt` where the profile resides:

```
example# cd /tmp/mnt
```

8. Test the `upgrade.prof` profile:

```
/usr/sbin/install.d/pfinstall -D upgrade.prof
```

EXAMPLE 2 Testing the `basic.prof` profile against the disk configuration on a Solaris 2.6 system.

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 2.6 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

EXAMPLE 3 Testing the `basic.prof` profile against the `535_test` disk configuration file.

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test -c /export/install basic.prof
```

EXAMPLE 3 Testing the basic .prof profile against the 535_test disk configuration file. (Continued)

EXIT STATUS

0	Successful (system rebooted).
1	Successful (system not rebooted).
2	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinst

SEE ALSO fdisk(1M), prtvtoc(1M), attributes(5)

Solaris 8 Advanced Installation Guide

WARNINGS If the -d or -D option is not specified, pfinstall may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

NOTES You have to test a profile on a system with the same platform type for which the profile was created.

SPARC To create a disk configuration file (-d option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the prtvtoc(1M) command to a file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 > 535_disk
```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

IA To create a disk configuration file (-d option) for an IA based system:

1. Locate an IA based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the fdisk(1M) command to a file:

```
example# fdisk -R -W 535_disk /dev/rdisk/c0t3d0p0
```

pfinstall(1M)

3. Append the output of the `prtvtoc(1M)` command to the disk configuration file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 >> 535_disk
```

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

To test a profile with a specific system memory size, set `SYS_MEMSIZE` to the specific memory size (in Mbytes) before running `pfinstall`:

```
example# SYS_MEMSIZE=memory_size
```

```
example# export SYS_MEMSIZE
```

NAME	pgxconfig, GFXconfig – configure the PGX32 (Raptor GFX) Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/pgxconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [try noconfirm nocheck]] [-file <i>machine</i> <i>system</i>] [-depth 8 24] [-24only] [-defaults] /usr/sbin/pgxconfig [-propt] [-prconf] /usr/sbin/pgxconfig [-help] [-res ?] /usr/sbin/pgxconfig [-i] </pre>
DESCRIPTION	<p>The <code>pgxconfig</code> utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named <code>GFXconfig</code>.</p> <p>The first form of <code>pgxconfig</code> shown in the synopsis above stores the specified options in the <code>OWconfig</code> file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the <code>OWconfig</code> file provides persistence of these options across window system sessions and system reboots.</p> <p>The second, third, and fourth forms, which invoke only the <code>-prconf</code>, <code>-propt</code>, <code>-help</code>, and <code>-res ?</code> options, do not update the <code>OWconfig</code> file. For the third form all other options are ignored.</p> <p>The <code>-i</code> option starts <code>pgxconfig</code> in interactive mode.</p> <p>Options may be specified for only one PGX32 (Raptor GFX) device at a time. Specifying options for multiple PGX32 (Raptor GFX) devices requires multiple invocations of <code>pgxconfig -i</code>.</p> <p>Only PGX32 (Raptor GFX)-specific options can be specified through <code>pgxconfig</code>. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the <code>openwin</code> command line. See the <code>Xsun(1)</code> manual page available with the <code>SUNWxwman</code> package.</p> <p>The user can also specify the <code>OWconfig</code> file that is to be updated. By default, the machine-specific file in the <code>/usr/openwin</code> directory tree is updated. The <code>-file</code> option can be used to specify an alternate file to use. For example, the system-global <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree can be updated instead.</p> <p>Both of these standard <code>OWconfig</code> files can only be written by root. Consequently, the <code>pgxconfig</code> program, which is owned by the root user, always runs with <code>setuid root</code> permission.</p>
OPTIONS	<p><code>-dev <i>device-filename</i></code> Specify the PGX32 (Raptor GFX) special file. The default is <code>/dev/fbs/gfxp0</code>, or <code>/dev/fbs/raptor0</code> if applicable.</p>

pgxconfig(1M)

`-file machine | system`

Specify which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-res video-mode [try | noconfirm | nocheck]`

Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for `video-mode` can be one of the following:

`widthxheightxrate`

The *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` prepended to the refresh rate rather than `x`. For example: `1280x1024@76`. The list can be obtained by running `pgxconfig` with the `-res ?` option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The `pgxconfig` utility will not permit you to set a resolution not supported by the board unless the `noconfirm` or `nocheck` option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the `nocheck` option is not specified.

Symbolic names

For convenience, the video modes listed below have symbolic names defined. Rather than the form `widthxheightxrate`, the symbolic name may be supplied as the argument to `-res`. If the symbolic name is `none`, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

<code>svga</code>	<code>1024x768x60</code>
<code>1152</code>	<code>1152x900x76</code>
<code>1280</code>	<code>1280x1024x76</code>
<code>vga</code>	<code>640x480x60</code>
<code>none</code>	default console resolution

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`noconfirm`

Using the `-res` option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the

	<p>monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of <code>pgxconfig</code> is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The <code>noconfirm</code> option instructs <code>pgxconfig</code> to bypass this confirmation and to program the requested video mode anyway. This option is useful when <code>pgxconfig</code> is being run from a shell script.</p>
<code>nocheck</code>	<p>If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies <code>noconfirm</code> as well.</p>
<code>try</code>	<p>This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissible answer is "n".</p>
<code>-res ?</code>	<p>Print the list of possible resolutions supported by the PGX32 and the monitor.</p>
<code>-24only</code>	<p>Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.</p>
<code>-defaults</code>	<p>Reset all option values to their default values.</p>
<code>-propt</code>	<p>Print the current values of all PGX32 (Raptor GFX) options in the <code>OWconfig</code> file specified by the <code>-file</code> option for the device specified by the <code>-dev</code> option. Print the values of options as they would be in the <code>OWconfig</code> file after the call to <code>pgxconfig</code> would have completed. The following is a typical display:</p> <pre> --- OpenWindows Configuration for /dev/fbs/gfxp0 --- OWconfig: machine Video Mode: not set </pre>
<code>-prconf</code>	<p>Print the PGX32 (Raptor GFX) hardware configuration. This following is a typical display:</p> <pre> --- Hardware Configuration for /dev/fbs/gfxp0 --- DAC: version 0x0 Type: Board: PROM: version 0x0 </pre>

                              800x600x60, 800x600x72, 800x600x75, 832x624x75,
                              1024x768x87, 1024x768x60, 1024x768x70, 1024x768x75,
                              1280x1024x75, 1280x1024x76, 1152x900x66, 1152x900x76,
                              1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
                              stereo
Current resolution setting: 1280x1024x76
Possible depths:
Current depth: 8
```

-help

Print a list of the `pgxconfig` command line options, along with a brief explanation of each.

-i

Start `pgxconfig` in interactive mode.

DEFAULTS

For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value, except for `-depth` and `-24` only.

A default value is used if a `PGX32` (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

```
-dev          /dev/fbs/gfxp0
-file         system
-res          none
```

The default of `none` for the `-res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

EXAMPLES

EXAMPLE 1 Switch the monitor type resolution.

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/pgxconfig -res 280x1024x76
```

FILES

```
/dev/fbs/gfxp0
device special file
```

`/usr/openwin/server/etc/OWconfig`
system configuration file

`/etc/openwin/server/etc/OWconfig`
machine configuration file

SEE ALSO *PGX32 Installation Manual*

picld(1M)

NAME	picld – PICL daemon
SYNOPSIS	<code>/usr/lib/picl/picld</code>
DESCRIPTION	<p>The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. <code>picld</code> maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode.</p> <p>Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the <code>libpicltree(3PICLTREE)</code> interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.</p>
PICL Tree	<p>The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is <code>picl</code>, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are <code>name</code> and <code>_class</code>, where <code>name</code> contains the name of the node, and the <code>_class</code> contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is <code>/</code> and the name of the root node of the sub-tree containing platform device nodes is <code>platform</code>.</p>
PICL plug-in Modules	<p>The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them.</p> <p>Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish:</p> <pre>/usr/platform/picl/plugins/'uname -i'/ /usr/platform/picl/plugins/'uname -m'/ /usr/lib/picl/plugins/</pre> <p>A plug-in module can specify its dependency on another plug-in module using the <code>-l</code> or <code>-R</code> linker option. The plug-ins are loaded by the daemon using <code>dlopen(3DL)</code> according to the specified dependencies. Each plug-in module must define a <code>.init</code> section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See <code>picld_plugin_register(3PICLTREE)</code> for additional information on plug-in registration.</p> <p>The plug-in modules use the <code>libpicltree(3PICLTREE)</code> interface to publish nodes and properties in the PICL tree so that clients can access them.</p> <p>The plug-in modules use the <code>picld_log(3PICLTREE)</code> function to log their messages to the system log file.</p> <p>When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to</p>

represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

EXIT STATUS `picld` does not return an exit status.

FILES

ping(1M)

NAME	ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts
SYNOPSIS	<pre>/usr/sbin/ping host [timeout] /usr/sbin/ping -s [-l -U] [-adlLnRv] [-A addr_family] [-c traffic_class] [-g gateway [-g gateway...]] [-F flow_label] [-I interval] [-i interface] [-P tos] [-p port] [-t ttl] host [data_size] [count]</pre>
DESCRIPTION	<p>The utility <code>ping</code> utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified <i>host</i> or network <i>gateway</i>. If <i>host</i> responds, <code>ping</code> will print</p> <pre>host is alive</pre> <p>on the standard output and exit. Otherwise, after <i>timeout</i> seconds, it will write</p> <pre>no answer from host</pre> <p>The default value of <i>timeout</i> is 20 seconds.</p> <p>When the <code>-s</code> flag is specified, <code>ping</code> sends one datagram per second (adjustable with <code>-I</code>) and prints one line of output for every ECHO_RESPONSE that it receives. No output is produced if there is no response. In this second form, <code>ping</code> computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default <i>data_size</i> is 56 bytes, or you can specify a size with the <i>data_size</i> command-line argument. If an optional <i>count</i> is specified, <code>ping</code> sends <code>ping</code> requests until it either sends <i>count</i> requests or receives <i>count</i> replies.</p> <p>When using <code>ping</code> for fault isolation, first <code>ping</code> the local host to verify that the local network interface is running.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-A addr_family</code> Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code>. Address family determines which protocol to use. For an argument of <code>inet</code>, IPv4 is used. For <code>inet6</code>, IPv6 is used.</p> <p>By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.</p> <p>Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code>, <code>ping</code> will use the IPv4 address associated with the hostname. If none exists, <code>ping</code> will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.</p>

	If the specified argument is <code>inet6</code> , <code>ping</code> will use the IPv6 address that is associated with the hostname. If none exists, <code>ping</code> will state that the host is unknown and exit.
<code>-a</code>	<code>ping</code> all of the addresses, both IPv4 and IPv6, of the multi-homed destination. The output will appear like <code>ping</code> has been run once for each IP address of the destination. If this option is used together with <code>-A</code> , <code>ping</code> probes only the addresses that are of the specified address family. When used with the <code>-s</code> option and <code>count</code> is not specified, <code>ping</code> continuously probes the destination addresses in a round robin fashion. If <code>count</code> is specified, <code>ping</code> will send <code>count</code> number of probes to each IP address of the destination and then exit.
<code>-c traffic_class</code>	Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of <code>traffic_class</code> set in the probe packet. This option is valid only on IPv6.
<code>-d</code>	Set the <code>SO_DEBUG</code> socket option.
<code>-F flow_label</code>	Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.
<code>-g gateway</code>	Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.
<code>-i interface_address</code>	Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. <code>interface_address</code> can be a literal IP address, for example, <code>10.123.100.99</code> , or an interface name, for example, <code>1e0</code> , or an interface index, for example <code>2</code> .
<code>-I interval</code>	Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the <code>-s</code> option.
<code>-l</code>	Use to send the probe packet to the given host and back again using loose source routing. Usually

ping(1M)

	specified with the <code>-R</code> option. If any gateways are specified using <code>-g</code> , they are visited twice, both to and from the destination. This option is ignored if the <code>-U</code> option is used.
<code>-L</code>	Turn off loopback of multicast packets. Normally, if there are members in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.
<code>-n</code>	Show network addresses as numbers. <code>ping</code> normally displays addresses as host names.
<code>-P tos</code>	Set the type of service (<i>tos</i>) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path may route the probe packet differently depending upon the value of <i>tos</i> that is set in the probe packet. This option is valid only on IPv4.
<code>-p port</code>	Set the base UDP <i>port</i> number used in probes. This option is used with the <code>-U</code> option. The default base <i>port</i> number is 33434. The <code>ping</code> utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.
<code>-r</code>	Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to <code>ping</code> a local host through an interface that has been dropped by the router daemon. See <code>in.routed(1M)</code> .
<code>-R</code>	Record route. Sets the IPv4 record route option, which will store the route of the packet inside the IPv4 header. The contents of the record route will only be printed if the <code>-v</code> and <code>-s</code> options are given. They will only be set on return packets if the target host preserves the record route option across echos, or the <code>-l</code> option is given. This option is valid only on IPv4.
<code>-s</code>	Send one datagram per second and collect statistics.
<code>-t ttl</code>	Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets is set with <code>ndd(1M)</code> using the <code>icmp_def_ttl</code> variable. The default time to live (hop limit) for multicast is one hop.
<code>-U</code>	Send UDP packets instead of ICMP (ICMP6) packets. <code>ping</code> sends UDP packets to consecutive ports

expecting to receive back ICMP (ICMP6)
PORT_UNREACHABLE from the target host.

-v Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

OPERANDS *host* The network host

EXAMPLES **EXAMPLE 1** Using ping With IPv6

This example shows ping sending probe packets to all the IPv6 addresses of the host london, one at a time. It sends an ICMP6 ECHO_REQUEST every second until user interrupts it.

```
istanbul% ping -s -A inet6 -a london
PING london: 56 data bytes
64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=2. ms
64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=1. ms
64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=1. ms
64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=1. ms
64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=1. ms
64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=1. ms
^C
----london PING Statistics----
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms)  min/avg/max = 1/1/2
```

EXIT STATUS The following exit values are returned:

0 Successful operation; the machine is alive.
non-zero An error has occurred; either a malformed argument has been specified, or the machine was not alive.

pkgadd(1M)

NAME	pkgadd – transfer software packages to the system
SYNOPSIS	pkgadd [-nv] [-a <i>admin</i>] [-d <i>device</i>] [[-M] -R <i>root_path</i>] [-r <i>response</i>] [-V <i>fs_file</i>] [<i>pkginst...</i>] pkgadd -s <i>spool</i> [-d <i>device</i>] [<i>pkginst...</i>]
DESCRIPTION	<p>pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d option, pkgadd looks in the default spool directory for the package (<i>var/spool/pkg</i>). Used with the -s option, it writes the package to a spool directory instead of installing it.</p> <p>Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning.</p> <p>To install these older packages (released prior to Solaris 2.4), set the following environment variable:</p> <pre>NONABI_SCRIPTS=TRUE</pre> <p>pkgadd will permit keyboard interaction throughout the installation as long as this environment variable is set.</p>
OPTIONS	<p>-a <i>admin</i> Define an installation administration file, <i>admin</i>, to be used in place of the default administration file. The token <i>none</i> overrides the use of any <i>admin</i> file, and thus forces interaction with the user. Unless a full path name is given, pkgadd first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgadd looks in the <i>/var/sadm/install/admin</i> directory for the administration file.</p> <p>-d <i>device</i> Install or copy a package from <i>device</i>. <i>device</i> can be a full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, <i>/var/tmp</i> or <i>/floppy/floppy_name</i>). It can also be a device alias (for example, <i>/floppy/floppy0</i>).</p> <p>-M Instruct pkgadd not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</p> <p>-n Installation occurs in non-interactive mode. The default mode is interactive.</p> <p>-r <i>response</i> Identify a file or directory which contains output from a previous <i>pkgask(1M)</i> session. This file supplies the interaction responses that would be requested by the package in interactive mode. <i>response</i> must be a full pathname.</p>

-R	<i>root_path</i>	Define the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <code>/export/root/client1</code>).
-s	<i>spool</i>	Write the package into the directory <i>spool</i> instead of installing it.
-v		Trace all of the scripts that get executed by <code>pkgadd</code> , located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts.
-V	<i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable.

When executed without options or operands, `pkgadd` uses `/var/spool/pkg` (the default spool directory).

OPERANDS	<i>pkginst</i>	The package instance or list of instances to be installed. The token <code>all</code> may be used to refer to all packages available on the source medium. The format <i>pkginst</i> . * can be used to indicate all instances of a package.
		The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

EXAMPLES **EXAMPLE 1** Installing a package from a Solaris CD-ROM.

The following example installs a package from a Solaris CD-ROM. You are prompted for the name of the package you want to install.

```
example% pkgadd -d /cdrom/cdrom0/s0/Solaris_2.6
```

EXIT STATUS	0	Successful execution.
	1	Fatal error.
	2	Warning.
	3	Interruption.
	4	Administration.
	5	Administration. Interaction is required. Do not use <code>pkgadd -n</code> .
	10	Reboot after removal of all packages.
	20	Reboot after removal of this package.

Application Packaging Developer's Guide

NOTES When transferring a package to a spool directory, the `-r`, `-n`, and `-a` options cannot be used.

The `-r` option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of `pkgadd`.

Each package would need a response file. If you create response files with the same name as the package (for example, `pkinst1` and `pkinst2`), then name the directory in which these files reside after the `-r`.

The `-n` option causes the installation to halt if any interaction is needed to complete it.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

NAME	pkgask – stores answers to a request script				
SYNOPSIS	pkgask [-d <i>device</i>] [-R <i>root_path</i>] -r <i>response</i> <i>pkginst...</i>				
DESCRIPTION	pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named <i>request</i>). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.				
OPTIONS	The following options are supported <ul style="list-style-type: none"> -d <i>device</i> Run the request script for a package on <i>device</i>. <i>device</i> can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory. -R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. -r <i>response</i> Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command. 				
OPERANDS	The following operands are supported: <ul style="list-style-type: none"> <i>pkginst</i> Specify the package instance, or list of instances for which request scripts will be created. The token <i>all</i> may be used to refer to all packages available on the source medium. 				
EXIT STATUS	0 Successful completion. >0 An error occurred.				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NOTES	The -r option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the				

pkgask(1M)

package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

NAME	pkgchk – check package installation accuracy
SYNOPSIS	<pre>pkgchk [-l -acfnqv] [-i file] [-p path...] [-R root_path] [[-m pkgmap [-e envfile]] [pkginst]...] pkgchk -d device [-l -fv] [-i file] [-M] [-p path...] [-v fs_file] [pkginst...]</pre>
DESCRIPTION	<p>pkgchk checks the accuracy of installed files or, by using the <code>-l</code> option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.</p> <p>The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.</p> <p>The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Audit the file attributes only and do not check file contents. Default is to check both. -c Audit the file contents only and do not check file attributes. Default is to check both. -d <i>device</i> Specify the device on which a spooled package resides. <i>device</i> can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, <code>/var/tmp</code> or <code>/dev/diskette</code>). -e <i>envfile</i> Request that the package information file named as <i>envfile</i> be used to resolve parameters noted in the specified pkgmap file. -f Correct file attributes if possible. If used with the <code>-x</code> option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the <code>-d</code> option calls out an uninstalled package, the <code>-f</code> option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that <code>setuid</code>, <code>setgid</code>, and sticky bits will not be set in the mode. -i <i>file</i> Read a list of path names from <i>file</i> and compare this list against the installation software database or the indicated pkgmap file. Path names which are not contained in <i>file</i> are not checked. -l List information on the selected files that make up a package. This option is not compatible with the <code>-a</code>, <code>-c</code>, <code>-f</code>, <code>-g</code>, and <code>-v</code> options.

pkgchk(1M)

	-m pkgmap	Check the package against the package map file, pkgmap.
	-M	Instruct pkgchk not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
	-n	Do not check volatile or editable files' contents. This should be used for most post-installation checking.
	-p <i>path</i>	Only check the accuracy of the path name or path names listed. <i>path</i> can be one or more path names separated by commas (or by white space, if the list is quoted).
	-q	Quiet mode. Do not give messages about missing files.
	-R <i>root_path</i>	Define the full name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).
	-v	Verbose mode. Files are listed as processed.
	-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
	-x	Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.
OPERANDS	<i>pkginst</i>	The package instance or instances to be checked. The format <i>pkginst . *</i> can be used to check all instances of a package. The default is to display all information about all installed packages. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\);
EXAMPLES	EXAMPLE 1 Using pkgchk for Displaying Package Installation Information	The following example displays package installation information for <i>/usr/bin/ls</i> : example% pkgchk -l -p /usr/bin/ls
EXIT STATUS	0	Successful completion.
	>0	An error occurred.
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:	

pkgchk(1M)

Application Packaging Developer's Guide

pkgrm(1M)

NAME	pkgrm – remove a package from the system
SYNOPSIS	pkgrm [-nv] [-a <i>admin</i>] [[-A -M] -R <i>root_path</i>] [-V <i>fs_file</i>] [<i>pkginst...</i>] pkgrm -s <i>spool</i> [<i>pkginst...</i>]
DESCRIPTION	<p>pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the <i>admin</i> file.</p> <p>The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the <i>-n</i> option.</p> <p>The <i>-s</i> option can be used to specify the directory from which spooled packages should be removed.</p> <p>Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.</p> <p>To remove these older packages (released prior to Solaris 2.4), set the following environment variable:</p> <pre>NONABI_SCRIPTS=TRUE</pre> <p>pkgrm will permit keyboard interaction throughout the removal as long as this environment variable is set.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a <i>admin</i> Use the installation administration file, <i>admin</i>, in place of the default <i>admin</i> file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the <i>/var/sadm/install/admin</i> directory for the administration file.-A Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.-M Instruct pkgrm not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.-n Non-interactive mode. If there is a need for interaction, the command will exit. Use of this option requires that at least one package instance be named upon invocation of the command.

<code>-R root_path</code>	Defines the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> .
<code>-s spool</code>	Remove the specified package(s) from the directory <i>spool</i> . The default directory for spooled packages is <code>/var/sadm/pkg</code> .
<code>-v</code>	Trace all of the scripts that get executed by <code>pkgrm</code> , located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts.
<code>-V fs_file</code>	Specify an alternative <i>fs_file</i> to map the client's file systems. Used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable.

OPERANDS The following operand is supported:

<i>pkginst</i>	Specifies the package to be removed. The format <i>pkginst</i> . * can be used to remove all instances of a package.
	The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

EXAMPLES **EXAMPLE 1** Removing all instances of SUNWjunk from client1.

The following example removes all instances of SUNWjunk from client1:

```
example% pkgrm -R /export/root/client1 SUNWjunk*
```

EXIT STATUS The following exit values are returned:

0	Successful execution.
1	Fatal error.
2	Warning.
3	Interruption.
4	Administration.
10	Reboot after removal of all packages.
20	Reboot after removal of this package.

Application Packaging Developer's Guide

NAME	pmadm – port monitor administration
SYNOPSIS	<pre>pmadm -a [-p <i>pmtag</i> -t <i>type</i>] -s <i>svctag</i> -i <i>id</i> -m <i>pmspecific</i> -v <i>ver</i> [-f <i>xu</i>] [-y <i>comment</i>] [-z <i>script</i>] pmadm -r -p <i>pmtag</i> -s <i>svctag</i> pmadm -e -p <i>pmtag</i> -s <i>svctag</i> pmadm -d -p <i>pmtag</i> -s <i>svctag</i> pmadm -l [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -L [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -g -p <i>pmtag</i> -s <i>svctag</i> [-z <i>script</i>] pmadm -g -s <i>svctag</i> -t <i>type</i> -z <i>script</i></pre>
DESCRIPTION	<p>pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See OPTIONS.</p> <p>pmadm performs the following functions:</p> <ul style="list-style-type: none"> ■ adds or removes a service ■ enables or disables a service ■ installs or replaces a per-service configuration script ■ prints requested service information <p>Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.</p>
OPTIONS	<p>The following options are supported:</p> <p>-a Add a service. pmadm adds an entry for the new service to the port monitor’s administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services.</p> <p>-d Disable a service. Add x to the flag field in the entry for the service <i>svctag</i> in the port monitor’s administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available.</p> <p>-e Enable a service. Remove x from the flag field in the entry for the service <i>svctag</i> in the port monitor administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available.</p>

pmadm(1M)

-f xu	<p>The -f option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the -f option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no utmpx entry is created for it. An -f option without a following argument is illegal.</p> <p>x Do not enable the service <i>svctag</i> available through port monitor <i>pmtag</i>.</p> <p>u Create a utmpx entry for service <i>svctag</i> available through port monitor <i>pmtag</i>.</p>
-g	<p>Print, install, or replace a per-service configuration script. The -g option with a -p option and a -s option prints the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -p option, a -s option, and a -z option installs the per-service configuration script contained in the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -s option, a -t option, and a -z option installs the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through any port monitor of type <i>type</i>. Other combinations of options with -g are invalid.</p>
-i <i>id</i>	<p><i>id</i> is the identity that is to be assigned to service <i>svctag</i> when it is started. <i>id</i> must be an entry in <i>/etc/passwd</i>.</p>
-l	<p>The -l option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings.</p> <p>-l By itself, the -l option lists all services on the system.</p> <p>-l -p <i>pmtag</i> Lists all services available through port monitor <i>pmtag</i>.</p> <p>-l -s <i>svctag</i> Lists all services with tag <i>svctag</i>.</p> <p>-l -p <i>pmtag</i>-<i>svctag</i> Lists service <i>svctag</i>.</p> <p>-l -t <i>type</i> Lists all services available through port monitors of type <i>type</i>.</p> <p>-l -t <i>type</i>-<i>svctag</i> Lists all services with tag <i>svctag</i> available through a port monitor of type <i>type</i>.</p> <p>Other combinations of options with -l are invalid.</p>
-L	<p>The -L option is identical to the -l option except that output is printed in a condensed format.</p>

<code>-m <i>pmspecific</i></code>	<i>pmspecific</i> is the port monitor-specific portion of the port monitor administrative file entry for the service.
<code>-p <i>pmtag</i></code>	Specifies the tag associated with the port monitor through which a service (specified as <code>-s <i>svctag</i></code>) is available.
<code>-r</code>	Remove a service. When <code>pmadm</code> removes a service, the entry for the service is removed from the port monitor's administrative file.
<code>-s <i>svctag</i></code>	Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.
<code>-t <i>type</i></code>	Specifies the the port monitor type.
<code>-v <i>ver</i></code>	Specifies the version number of the port monitor administrative file. The version number may be given as <code>-v '<i>pmspec</i> -v'</code> where <i>pmspec</i> is the special administrative command for port monitor <i>pmtag</i> . This special command is <code>ttymon</code> for <code>ttymon</code> and <code>nlsadmin</code> for <code>listen</code> . The version stamp of the port monitor is known by the command and is returned when <i>pmspec</i> is invoked with a <code>-V</code> option.
<code>-y <i>comment</i></code>	Associate <i>comment</i> with the service entry in the port monitor administrative file.
<code>-z <i>script</i></code>	Used with the <code>-g</code> option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (<code>-g</code> alone). Then the copy is edited. Finally, the copy is put in place over the existing script (<code>-g</code> with <code>-z</code>).

Options that request information write the requested information to the standard output. A request for information using the `-l` option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the `-L` option prints the information in colon-separated fields; missing fields are indicated by two successive colons. `#` is the comment character.

EXAMPLES **EXAMPLE 1** Using the `pmadm` Command

Add a service to a port monitor with tag `pmtag`. Give the service the tag `svctag`. Port monitor-specific information is generated by `specpm`. The service defined by `svctag` will be invoked with identity `root`.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

Add a service with service tag `svctag`, identity `guest`, and port monitor-specific information generated by `specpm` to all port monitors of type `type`:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

pmadm(1M)

EXAMPLE 1 Using the pmadmCommand (Continued)

Remove the service svctag from port monitor pmtag:

```
pmadm -r -p pmtag -s svctag
```

Enable the service svctag available through port monitor pmtag:

```
pmadm -e -p pmtag -s svctag
```

Disable the service svctag available through port monitor pmtag:

```
pmadm -d -p pmtag -s svctag
```

List status information for all services:

```
pmadm -l
```

List status information for all services available through the port monitor with tag ports:

```
pmadm -l -p ports
```

List the same information in condensed format:

```
pmadm -L -p ports
```

List status information for all services available through port monitors of type listen:

```
pmadm -l -t listen
```

Print the per-service configuration script associated with the service svctag available through port monitor pmtag:

```
pmadm -g -p pmtag -s svctag
```

EXIT STATUS The following exit values are returned:

0 Successful operation.

>0 Operation failed.

pmconfig(1M)

NAME	pmconfig – Configure the Power Management system
SYNOPSIS	<code>/usr/sbin/pmconfig [-r] [-f file]</code>
DESCRIPTION	<p>The <code>pmconfig</code> utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using <code>pmconfig</code> only if he is allowed to do so according to <code>PMCHANGEPERM</code> keyword of <code>/etc/default/power</code>. User has permission to change the suspend-resume configuration using <code>pmconfig</code> only if he is allowed to do so according to the <code>CPRCHANGEPERM</code> keyword of <code>/etc/default/power</code>. See FILES section below for a description of the <code>PMCHANGEPERM</code> and <code>CPRCHANGEPERM</code> keywords of <code>/etc/default/power</code>.</p> <p>Based on user permissions, <code>pmconfig</code> first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from <code>/etc/power.conf</code> and issues the commands to activate the new configuration. The <code>pmconfig</code> utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the <code>/etc/power.conf</code> file. For editing changes made to the <code>/etc/power.conf</code> file to take effect, users must run <code>pmconfig</code>.</p> <p>The preferred interface for changing Power Management and suspend-resume configuration is <code>dtpower(1M)</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-r</code> Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.<code>-f file</code> Based on user permissions, <code>pmconfig</code> first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from <i>file</i> instead of <code>/etc/power.conf</code> and issues the commands to activate the new configuration. If <code>pmconfig</code> was successful in setting the Power Management and/or suspend-resume configuration, the corresponding configuration in <code>/etc/power.conf</code> is replaced with the configuration in <i>file</i>.
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Upon successful completion>0 An error occurred
FILES	<ul style="list-style-type: none"><code>/etc/power.conf</code> System Power Management configuration file<code>/etc/default/power</code> File that controls permissions for system's Power Management and suspend-resume features. The <code>PMCHANGEPERM</code> keyword controls the Power Management configuration permissions, while the

CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.

Allowed values are:

all	Any user can change the configuration.
-	No one except super-user can change the configuration.
<user1, user2, ...>	A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in < and > characters.
console-owner	A user who owns the system console device node or a super-user can change the configuration.

The default values are PMCHANGEPERM=console-owner and CPRCHANGEPERM=console-owner.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu
Interface stability	Unstable

SEE ALSO `dtpower(1M)`, `powerd(1M)`, `power.conf(4)`, `attributes(5)`, `cpr(7)`, `pm(7D)`

Using Power Management

DIAGNOSTICS If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.

pntadm(1M)

NAME	pntadm – DHCP network table management utility
SYNOPSIS	<pre>pntadm -C [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -A <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client_ID</i>] [-m [-y] <i>macro</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -M <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client ID</i>] [-m [-y] <i>macro</i>] [-n <i>new_client_IP_address</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -D <i>name_IP_address</i> [-y] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -P [-v] [-x] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -R [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -L [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] pntadm -B [-v] [<i>batchfile</i>]</pre>
DESCRIPTION	<p>The pntadm command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see dhcp_network(4).</p> <p>pntadm can be run as root or by other users assigned to the DHCP Management profile. See rbac(5) and user_attr(4).</p> <p>If the networks you want to add are subnetted, you need to update the netmasks(4) table.</p> <p>One of the following options (function flags) must be specified with the pntadm command: -A, -B, -C, -D, -L, -M, -P, or -R.</p>
OPTIONS	<p>The following options are supported:</p> <p>-A <i>name_IP_address</i> Add a client entry with hostname or client IP address, <i>name_IP_address</i>, to the named DHCP network table.</p> <p>The following sub-options are optional:</p> <ul style="list-style-type: none">-c <i>comment</i> Comment text. The default is NULL.-e <i>mm/dd/yyyy</i> Absolute lease. The default is 0.-f <i>num</i> <i>keywords</i> Flag value. The default is 00.

The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or 00

Server manager's assignment.

PERMANENT or 01

Lease on entry is permanent.

MANUAL or 02

Administrator managed assignment.

UNUSABLE or 04

Entry is not valid.

BOOTP or 08

Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see `dhcp_network(4)`.

-h *client_hostname*

Client hostname. The default is NULL.

When the -h option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files, NIS+ or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

-i *client_ID* [-a]

Client identifier [-a]. The default is 00.

The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m *macro* [-y]

Macro name. Default is UNKNOWN.

The -m option modified with -y verifies the existence of the named macro in the `dhcptab` table before adding the entry.

-s *server*

Server IP or name. Default is system name (uname -n).

-B

Activate batch mode. `pntadm` will read from the specified file or from standard input a series of `pntadm`

pntadm(1M)

commands and execute them within the same process. Processing many pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts.

The following sub-option is optional:

-v

Display commands to standard output as they are processed.

-C

Create the DHCP network table for the network specified by *network*. See OPERANDS. For details, see dhcp_network(4) and networks(4).

-D *name_IP_address*

Delete the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. (See dhcp_network(4).)

The following sub-option is optional:

-Y

Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

-L

List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.

-M *name_IP_address*

Modify the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. See dhcp_network(4). The default for the sub-options is what they currently are set to.

The following sub-options are optional.

-c *comment*

New comment text.

-e *mm/dd/yy*

New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.

-f *num | keyboard*

New flag value, see explanation following the description of the -A option.

-h *host_name*

New client hostname.

The `-h` option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.

- `-i client_ID`
New client identifier [-a].
- `-m macro [-y]`
Macro name defined in `dhcptab`.
- `-n new_client_IP_address`
New IP address.
- `-s server`
New server IP or name.

For more detailed description of the sub-options and flag values, see `dhcp_network(4)`.

`-P` Display the named DHCP network table. See `dhcp_network(4)`.

The following sub-options are optional:

- `-v` Display lease time in full verbose format.
- `-x` Display lease time in raw format.

`-p path` Override the `dhcpsvc.conf(4)` configuration value for data store resource path, *path* See `dhcpsvc.conf(4)`

`-R` Remove the named DHCP network table. See `dhcp_network(4)`.

`-r data_store_resource` Override the `/etc/inet/dhcpsvc.conf` configuration value for `RESOURCE=` with the *data_store_resource* specified. See the `dhcpsvc.conf(4)` man page for more details on resource type, and the *Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores.

`-u uninterpreted` Data which will be ignored by `pntadm`, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

OPERANDS The following operand is supported:

pntadm(1M)

network The network address or network name which corresponds to the dhcp network table. See dhcp_network(4).

EXAMPLES **EXAMPLE 1** Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your networks(4) table, you can use that value rather than the dotted Internet Address notation.

```
example# pntadm -C 10.0.0.0
```

EXAMPLE 2 Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the files resource in the /var/mydhcp directory:

```
example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

EXAMPLE 3 Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

```
example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT + MANUAL' 10.0.0.0
```

EXAMPLE 4 Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the hosts(4) table called myclient:

```
example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

EXAMPLE 5 Setting the Client ID as ASCII

The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

```
example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

EXAMPLE 6 Deleting the myclientEntry from the 10.0.0.0 Table

The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 6 Deleting the myclientEntry from the 10.0.0.0 Table (Continued)

EXAMPLE 7 Removing the Named DHCP Network Table

The following command removes the named DHCP network table in the NIS+ directory specified:

```
example# pntadm -r SUNWnisplus -p Test.Nis.Plus. -R 10.0.0.0
```

EXAMPLE 8 Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 9 Executing pntadm Commands in Batch Mode

The following command runs a series of pntadm commands contained in a batch file:

```
example# pntadm -B addclients
```

EXIT STATUS

0	Successful completion.
1	Object already exists.
2	Object does not exist.
3	Non-critical error.
4	Critical error.

NAME	ports – creates /dev entries and inittab entries for serial lines
SYNOPSIS	<code>/usr/sbin/ports [-r rootdir]</code>
DESCRIPTION	<p>devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of ports.</p> <p>The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically.</p> <p>ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following:</p> <ol style="list-style-type: none"> 1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters. 2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports. 3. Creates new /dev/term and /dev/cua links for new serial devices. 4. Invokes sacadm(1M) to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly. <p>If the configuration has not changed, ports exits without doing anything.</p> <p>ports is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed. When invoking ports manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.</p>
Notice to Driver Writers	<p>ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling ddi_create_minor_node(9F).</p> <ul style="list-style-type: none"> ■ The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device. ■ The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0,cu. ■ The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the

ports(1M)

device is named *a*, the second is named *b*, the third is named *c*, for all ports on the device (or up through port *z*).

- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with *,cu*. For example, the minor name for the first dialout port on the on-board serial device is *a,cu*.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`.

OPTIONS `-r rootdir` Causes `ports` to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under *rootdir*, not directly under `.`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the *rootdir*.

EXAMPLES **EXAMPLE 1** Creating the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function.

The following demonstrates creating the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function.

```
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */ #define XKNUMPORTS            8
#define XKMINORNUM(i, p)        ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p)    ((i) << 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name, "%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}
```

EXAMPLE 1 Creating the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function. (Continued)

EXAMPLE 2 Installing the `xkserial` port driver on a SPARCstation 20.

Installing the `xkserial` port driver on a SPARCstation 20 (with the driver controlling the fictional XKSerial 8 port serial board) and performing a reconfiguration-boot would create the following special files in `/devices`.

```
# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/xkserial@f,800000/
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
crw-r----- 1 root sys 32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r----- 1 root sys 32, 17 Aug 29 00:02 xkserial@2000:1
crw-r----- 1 root sys 32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xkserial@2000:2
crw-r----- 1 root sys 32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r----- 1 root sys 32, 19 Aug 29 00:02 xkserial@2000:3
crw-r----- 1 root sys 32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xkserial@2000:4
crw-r----- 1 root sys 32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r----- 1 root sys 32, 21 Aug 29 00:02 xkserial@2000:5
crw-r----- 1 root sys 32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r----- 1 root sys 32, 22 Aug 29 00:02 xkserial@2000:6
crw-r----- 1 root sys 32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xkserial@2000:7
crw-r----- 1 root sys 32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

`/dev/term` will contain symbolic links to the serial port device nodes in `/devices`

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[...]/xkserial@2000:0
/dev/term/1 -> ../../devices/[...]/xkserial@2000:1
/dev/term/2 -> ../../devices/[...]/xkserial@2000:2
/dev/term/3 -> ../../devices/[...]/xkserial@2000:3
/dev/term/4 -> ../../devices/[...]/xkserial@2000:4
/dev/term/5 -> ../../devices/[...]/xkserial@2000:5
/dev/term/6 -> ../../devices/[...]/xkserial@2000:6
/dev/term/7 -> ../../devices/[...]/xkserial@2000:7
```

and `/dev/cua` will contain symbolic links to the dialout port device nodes in `/devices`

```
# ls -l /dev/cua
/dev/cua/0 -> ../../devices/[...]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[...]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[...]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[...]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[...]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[...]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[...]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[...]/xkserial@2000:7,cu
```

Writing Device Drivers

NAME	powerd – Power manager daemon
SYNOPSIS	<code>/usr/lib/power/powerd [-n]</code>
DESCRIPTION	<p>The <code>powerd</code> daemon is started by <code>pmconfig(1M)</code> to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend.</p> <p>Immediately prior to system shutdown, the daemon notifies <code>syslogd(1M)</code> of the shutdown, which broadcasts a notification.</p>
OPTIONS	<p>The following option is supported:</p> <p><code>-n</code> No broadcast mode. The daemon silently shuts down the system without notifying <code>syslogd(1M)</code>.</p>
FILES	<code>/etc/power.conf</code> Power Management configuration information file
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu

Using Power Management

pppd(1M)

NAME	pppd – point to point protocol daemon						
SYNOPSIS	pppd [<i>tty_name</i>] [<i>speed</i>] [<i>options</i>]						
DESCRIPTION	<p>The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.</p> <p>The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or “IPCP” or “IPV6CP.”)</p> <p>The pppd daemon is part of Solaris PPP 4.0, an implementation of the Point-to-Point Protocol (PPP) that is based on the Australian National University PPP. For information on licensing terms, refer to the incorporated materials at <code>/var/sadm/pkg/SUNWpppdu/install/copyright</code>.</p>						
OPTIONS	The following sections discuss the pppd options:						
Options Files	<p>Options are taken from files and the command line. pppd reads options from the files <code>/etc/ppp/options</code>, <code>\$HOME/.ppprc</code> and <code>/etc/ppp/options.ttyname</code> (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the <code>options.ttyname</code> file is read.) To form the name of the <code>options.ttyname</code> file, the initial <code>/dev/</code> is removed from the terminal name, and any remaining forward slash characters (“/”) are replaced with dots. For example, with serial device <code>/dev/cua/a</code>, option file <code>/etc/ppp/options.cua.a</code> is read.</p> <p>An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes (“”). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the <code>file</code> or <code>call</code> options within an options file.</p>						
Frequently Used Options	<table><tr><td><code><tty_name></code></td><td>Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.</td></tr><tr><td><code><speed></code></td><td>Set the baud rate to <code><speed></code> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.</td></tr><tr><td><code>asynctest <map></code></td><td>Set the <code>asynctest</code> character map to <code><map></code>. The map describes which control characters cannot be</td></tr></table>	<code><tty_name></code>	Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.	<code><speed></code>	Set the baud rate to <code><speed></code> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.	<code>asynctest <map></code>	Set the <code>asynctest</code> character map to <code><map></code> . The map describes which control characters cannot be
<code><tty_name></code>	Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.						
<code><speed></code>	Set the baud rate to <code><speed></code> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.						
<code>asynctest <map></code>	Set the <code>asynctest</code> character map to <code><map></code> . The map describes which control characters cannot be						

	successfully received over the serial line. <code>pppd</code> asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple <code>asynctest</code> options are given, the values are ORed together. If no <code>asynctest</code> option is given, <code>pppd</code> attempts to negotiate a value of 0. If the peer agrees, this disables escaping of the standard control characters. Use the <code>default-asynctest</code> option to disable negotiation and escape all control characters.
<code>auth</code>	Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the <code>auth</code> or the <code>noauth</code> option is not specified, <code>pppd</code> allows the peer to use only those IP addresses to which the system does not already have a route.
<code>call name</code>	Read options from the file <code>/etc/ppp/peers/name</code> . This file may contain privileged options, including <code>noauth</code> , even if <code>pppd</code> is not being run by root. The <code>name</code> string may not begin with a slash ("/") or include consecutive periods (". . .") as a pathname component.
<code>callback number</code>	Request a callback to the given telephone number using Microsoft CBCP.
<code>connect script</code>	Use the executable or shell command specified by <code>script</code> to set up the serial line. This script would typically use the <code>chat(1M)</code> program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<code>crtstcts</code>	Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the <code>crtstcts</code> , <code>nocrtstcts</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.

pppd(1M)

<code>defaultroute</code>	Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the <code>nodefaltroute</code> option is specified.
<code>disconnect script</code>	Run the executable or shell command specified by <i>script</i> after <code>pppd</code> terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. <code>disconnect</code> is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<code>escape xx,yy,...</code>	Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its <code>async</code> control character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the <code>escape</code> option, unlike the <code>asyncmap</code> option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 - 0x3f or 0x5e.
<code>file name</code>	Read options from file <i>name</i> . If this option is used on the command line or in <code>\$HOME/.ppprc</code> , the file must be readable by the user invoking <code>pppd</code> . See Options Files for a list of files that <code>pppd</code> always reads, regardless of the use of this option.
<code>init script</code>	Run the executable or shell command specified by <i>script</i> to initialize the serial line. This script would typically use the <code>chat(1M)</code> program to configure the modem to enable auto answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.
<code>lock</code>	Directs <code>pppd</code> to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.
<code>mru n</code>	Set the Maximum Receive Unit (MRU) value to <i>n</i> . <code>pppd</code> asks the peer to send packets of no more than <i>n</i> bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.

mtu <i>n</i>	Set the MTU [Maximum Transmit Unit] value to <i>n</i> . Unless the peer requests a smaller value via MRU negotiation, pppd requests the kernel networking code to send data packets of no more than <i>n</i> bytes through the PPP network interface. For IPv6, MTU must be at least 1280.
passive	Enables the "passive" option in the LCP. With this option, pppd attempts to initiate a connection; if no reply is received from the peer, pppd waits passively for a valid LCP packet instead of exiting, as it would without this option.
Options	<p><code><local_IP_address>:<remote_IP_address></code> Set the local and/or remote interface IP addresses. Either one may be omitted. The IP addresses are specified with a host name or in decimal dot notation, for example: 10.1.2.3. The default local address is the first IP address of the system unless the <code>noipdefault</code> option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, pppd will not accept a different value from the peer in the IPCP negotiation unless the <code>ipcp-accept-local</code> and/or <code>ipcp-accept-remote</code> options are given, respectively.</p> <p><code>allow-fcs fcs-type</code> Set allowable FCS type(s) for data to peer. The <i>fcs-type</i> is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.</p> <p><code>allow-ip address(es)</code> Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed for each element of the list of allowed IP addresses in the secrets files. See the Authentication section more more details.</p> <p><code>bsdcomp nr,nt</code> Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of <i>nr</i> bits, and agree to compress packets sent to the peer with a maximum code size of <i>nt</i> bits. If <i>nt</i> is not specified, it defaults to the value given for <i>nr</i>. Values in the range 9 to 15 may be used for <i>nr</i> and <i>nt</i>; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for <i>nr</i> or <i>nt</i> disables compression in the corresponding direction. Use <code>nobsdcomp</code> or <code>bsdcomp 0</code> to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.</p> <p><code>cdtrcts</code> Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the <code>crtcts</code>, <code>nocrtcts</code>, <code>cdtrcts</code> or <code>nocdtrcts</code></p>

pppd(1M)

option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

`chap-interval n`

If this option is given, `pppd` will rechallenge the peer every *n* seconds.

`chap-max-challenge n`

Set the maximum number of CHAP challenge transmissions to *n* (default 10).

`chap-restart n`

Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

`connect-delay n`

Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, `pppd` begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the `connect` or `pty` option is used.

`datarate n`

Set maximum data rate to *n* (in bytes per second) when using the `pty`, `notty`, `record`, or `socket` options.

`debug`

Enables connection debugging facilities. If this option is given, `pppd` logs the contents of all control packets sent or received in a readable form. The packets are logged through `syslog` with facility `daemon` and level `debug`. This information can be directed to a file by configuring `/etc/syslog.conf` appropriately.

`default-asynctmap`

Disable `asynctmap` negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

`default-fcs`

Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

`default-mru`

Disable MRU [Maximum Receive Unit] negotiation. With this option, `pppd` uses the default MRU value of 1500 bytes for the transmit and receive directions.

`deflate nr,nt,e`

Request that the peer compress packets that it sends, using the `deflate` scheme, with a maximum window size of 2^{*nr} bytes, and agree to compress packets sent to the peer with a maximum window size of 2^{*nt} bytes and effort level of *e* (1 to 9). If *nt* is not specified, it defaults to the value given for *nr*. If *e* is not specified, it defaults to 6. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression

dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nodeflate` or `deflate 0` to disable `deflate` compression entirely. (Note: `pppd` requests `deflate` compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

`demand`

Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. `pppd` initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, `pppd` connects to the peer and performs negotiation, authentication and other actions. When completed, `pppd` passes data packets across the link. The `demand` option implies the `persist` option. If this behaviour is not desired, use the `nopersist` option after the `demand` option. The `idle` and `holdoff` options can be used in conjunction with the `demand` option.

`domain d`

Append the domain name *d* to the local host name for authentication purposes. For example, if `gethostname()` returns the name `porsche`, but the fully qualified domain name is `porsche.Quotron.COM`, you could specify `domain Quotron.COM`. `pppd` uses the name `porsche.Quotron.COM` for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

`endpoint endpoint-value`

Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period ("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

`fcs fcs-type`

Set FCS type(s) desired for peer data. The *fcs-type* is a comma-separated list of `crc16`, `crc32`, `null`, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

`hide-password`

When logging the contents of PAP packets, this option causes `pppd` to exclude the password string from the log. This is the default.

pppd(1M)

`holdoff` *n*

Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the `persist` or `demand` option is used. The holdoff period is not applied if the link is terminated because it was idle.

`ident` *string*

Set the LCP Identification string. The default value is a version string similar to that printed by the `--version` option.

`idle` *n*

Specifies that pppd disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the `persist` option without the `demand` option.

`ipcp-accept-local`

With this option, pppd accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

`ipcp-accept-remote`

With this option, pppd accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

`ipcp-max-configure` *n*

Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

`ipcp-max-failure` *n*

Set the maximum number of IPCP Configure-NAKs returned before sending Configure-Rejects instead to *n* (default 10).

`ipcp-max-terminate` *n*

Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

`ipcp-restart` *n*

Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipparam` *string*

Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the Scripts section.

`ipv6` *<local_interface_identifier>*, *<remote_interface_identifier>*

Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: dead:beef). If the `ipv6cp-use-ipaddr` option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The `ipv6cp-use-persistent` option can be used instead of the `ipv6 <local>`, `<remote>` option.

`ipv6cp-accept-local`

Accept peer's interface identifier for the local link identifier.

- `ipv6cp-max-configure n`
Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).
- `ipv6cp-max-failure n`
Set the maximum number of IPv6CP Configure-NAKs returned before sending Configure-Rejects instead to *n* (default 10).
- `ipv6cp-max-terminate n`
Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).
- `ipv6cp-restart n`
Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).
- `ipv6cp-use-ipaddr`
If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with `lcp-accept-local` if the local IPv6 identifier is unspecified or with `lcp-accept-remote` if the remote IPv6 identifier is unspecified.)
- `ipv6cp-use-persistent`
Use uniquely-available persistent value for link local address.
- `kdebug n`
Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the `debug` option instead.
- `lcp-echo-failure n`
If this option is given, `pppd` presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.
- `lcp-echo-interval n`
If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.
- `lcp-max-configure n`
Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

pppd(1M)

`lcp-max-failure n`
Set the maximum number of LCP Configure-NAKs returned before starting to send Configure-Rejects instead to *n* (default 10).

`lcp-max-terminate n`
Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

`lcp-restart n`
Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

`linkname name`
Sets the logical name of the link to *name*. pppd creates a file named `ppp-name.pid` in `/var/run` containing its process ID. This is useful in determining which instance of pppd is responsible for the link to a given peer system. This is a privileged option.

`local`
Do not use modem control lines. With this option, pppd ignores the state of the CD (Carrier Detect) signal from the modem and changes the state of the DTR (Data Terminal Ready) signal.

`logfd n`
Send log messages to file descriptor *n*. pppd sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the `logfile` option are mutually exclusive. By default pppd sends log messages to `stdout` (file descriptor 1) unless the serial port is open on `stdout`.

`logfile filename`
Append log messages to the file *filename* (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked pppd.

`login`
Use the system password database for authenticating the peer using PAP, and record the user in the system `wtmp` file. Note that the peer must have an entry in the `/etc/ppp/pap-secrets` file and the system password database to be allowed access.

`maxconnect n`
Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

`maxfail n`
Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

`modem`
Use the modem control lines. This option is the default. With this option, pppd waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR

(Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns *<addr>*

If `pppd` is acting as a server for Microsoft Windows clients, this option allows `pppd` to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. (This option is present in some older versions of `pppd` under the name `dns-addr`.)

ms-lanman

If `pppd` connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins *<addr>*

If `pppd` acts as a server for Microsoft Windows or "Samba" clients, this option allows `pppd` to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address.

name *name*

Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, `pppd` uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the `user` option, *name* is used as the name to send to the peer when authenticating the local system. (Note that `pppd` does not append the domain name to *name*.)

no-accm-test

Disable use of `asynmap` (ACCM) checking using LCP Echo-Request messages. If the `lcp-echo-failure` is used on an asynchronous line, `pppd` includes all control characters in the first *n* LCP Echo-Request messages. If the `asynmap` is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp

Disable HDLC Address/Control compression in both directions (send and receive).

noauth

Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp

Disables BSD-Compress compression; `pppd` will not request or agree to compress packets using the BSD-Compress scheme.

noccp

Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from `pppd` for CCP negotiation.

pppd(1M)

`nocrtscts`

Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` options are not given, the hardware flow control setting for the serial port is left unchanged.

`nocdtrcts`

This option is a synonym for `nocrtscts`. Either option will disable both forms of hardware flow control.

`nodefaultroute`

Disable the `defaultroute` option. You can prevent users from creating default routes with `pppd` by placing this option in the `/etc/ppp/options` file.

`nodeflate`

Disables deflate compression; `pppd` will not request or agree to compress packets using the deflate scheme.

`nodeflatedraft`

Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression.

`nodetach`

Do not detach from the controlling terminal. Without this option, `pppd` forks to become a background process if a serial device other than the terminal on the standard input is specified.

`noendpoint`

Do not send or accept the Multilink Endpoint Discriminator option.

`noident`

Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, `pppd` sends LCP Code-Reject in response to received LCP Identification messages.)

`noip`

Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from `pppd` for IPCP negotiation.

`noipv6`

Disable IPv6CP negotiation and IPv6 communication. Use this option only if the peer has bugs or becomes confused by requests from `pppd` for IPv6CP negotiation.

`noipdefault`

Disables the default behaviour when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

`nolog`

Do not send log messages to a file or file descriptor. This option cancels the `logfd` and `logfile` options. `nologfd` acts as an alias for this option.

nomagic

Disable magic number negotiation. With this option, `pppd` cannot detect a looped-back line. Use this option only if the peer has bugs.

nopam

This privileged option disables use of pluggable authentication modules. If this option is specified, `pppd` reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp

Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist

Exit once a connection has been made and terminated. This is the default unless the `persist` or `demand` option is specified.

noplink

Cause `pppd` to use `I_LINK` instead of `I_PLINK`. This is the default. When `I_LINK` is used, the system cleans up terminated interfaces (even when `SIGKILL` is used) but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use the `plink` option if `ifconfig(1M)` `modinsert`, `modremove` or `unplumb` support is needed.

nopredictor1

Do not accept or agree to Predictor-1 compression.

noproxyarp

Disable the `proxyarp` option. If you want to prevent users from creating proxy ARP entries with `pppd`, place this option in the `/etc/ppp/options` file.

notty

Normally, `pppd` requires a terminal device. With this option, `pppd` allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. `pppd` creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, `pppd` transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the `ppp` interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj

Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp

Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, `pppd` does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so.

pppd(1M)

pam

This privileged option enables use of PAM. If this is specified, `pppd` uses the `pam(3PAM)` framework for user authentication with a service name of "ppp." The default is not to use PAM.

papcrypt

Indicates that `pppd` should not accept a password which, before encryption, is identical to the secret from the `/etc/ppp/pap-secrets` file.

pap-max-authreq *n*

Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

pap-restart *n*

Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

pap-timeout *n*

Set the maximum time that `pppd` waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit).

password *string*

Password string for authentication to the peer.

persist

Do not exit after a connection is terminated; instead try to reopen the connection.

plink

Cause `pppd` to use `I_PLINK` instead of `I_LINK`. The default is to use `I_LINK`, which cleans up terminated interface (even if `SIGKILL` is used), but does not allow `ifconfig(1M)` to unplug PPP streams or insert or remove modules dynamically. Use this option if `ifconfig(1M)` `modinsert/modremove/unplug` support is needed. See the `plumbed` option.

plugin *filename*

Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

plumbed

This option indicates that `pppd` should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older `aspppd` implementation and may be helpful when `pppd` is used with external applications that use `ifconfig(1M)`.

pppmux *timer*

Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

privgroup *group-name*

Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use `pppd`

to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the kmem or disk group.

proxyarp

Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty *script*

Specifies that the command *script*, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the *record* option is used in conjunction with the *pty* option, the child process will have pipes on its standard input and output.)

receive-all

With this option, pppd accepts all control characters from the peer, including those marked in the *receive asyncmap*. Without this option, pppd discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs.

record *filename*

Directs pppd to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the *pppdump(1M)* program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the *debug* option.

remotename *name*

Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap

With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap

Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

pppd(1M)

refuse-mschapv2

Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap

With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap

Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap

Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2

Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap

Require the peer to authenticate itself using PAP authentication.

show-password

When logging contents of PAP packets, this option causes pppd to show the password string in the log message.

silent

With this option, pppd will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the 'passive' option with older versions of pppd.

small-accm-test

When checking the `asynctest` (ACCM) setting, pppd uses all 256 possible values by default. See `no-accm-test`. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket *host : port*

Connect to given host and port using TCP and run PPP over this connection.

sync

Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd with this option must have sync support. Currently supports `zs` drivers.

unit *n*

Set PPP interface unit number to *n*, if possible.

updetach

With this option, pppd detaches from its controlling terminal after establishing the ppp connection. When this is specified, messages sent to `stderr` by the connect script, usually `chat(1M)`, are directed to pppd's standard output.

usehostname

Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the name option. Because the name option is privileged, this option is normally not needed.

usepeerdns

Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the `/etc/ppp/ip-up` script in the environment variables DNS1 and DNS2. In addition, pppd creates an `/etc/ppp/resolv.conf` file containing one or two nameserver lines with the address(es) supplied by the peer.

user *name*

Sets the name used for authenticating the local system to the peer to *name*.

vj-max-slots *n*

Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

welcome *script*

Run the executable or shell command specified by *script* before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.

xonxoff

Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options

The following options are obsolete:

+ua *name*

Read a PAP user name and password from the file *name*. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.

+ipv6

Enable IPv6 and IPv6CP without specifying interface identifiers.

--version

Show version number and exit.

--help

Show brief help message and exit.

EXTENDED DESCRIPTION**Security**

The following sections discuss miscellaneous features of pppd:

pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations

pppd(1M)

are privileged. Privileged options are only accepted in files that are under the control of the system administrator or when `pppd` is being run by root.

By default, `pppd` allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the `auth` option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running `pppd`, either on the command line, in the user's `$HOME/.ppprc` file, or in an options file read using the `file` option. Privileged options may be used in `/etc/ppp/options` file or in an options file read using the `call` option. If `pppd` is run by the root user, privileged options can be used without restriction. If the `/etc/ppp/options` file does not exist, then only root may invoke `pppd`. The `/etc/ppp/options` file must be created (but may be empty) to allow ordinary non-root users to access `pppd`.

When opening the device, `pppd` uses the invoking user's user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, `/etc/ppp/options` or an options file read using the `call` option, `pppd` uses full root privileges when opening the device. Thus, by creating an appropriate file under `/etc/ppp/peers`, the system administrator can allow users to establish a PPP connection via a device that they would not normally have access to. Otherwise `pppd` uses the invoking user's real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

`pppd` supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, `pppd` authenticates if requested and does not require authentication from the peer. However, `pppd` does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that display the secret and the client and server names. Often, the fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign (“@”) is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen (“-”). To allow any address, use “*”. An address starting with an exclamation point (“!”) indicates that the specified address is not acceptable. An address may be followed by “/” and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits). In this form, the address may be followed by a plus sign (“+”) to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer’s name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the `domain` option is used. The default can be overridden with the `name` option unless the `usehostname` option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the `user` option. If the `user` option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer’s name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer’s name from the options specified by the user. The user can specify the peer’s name directly with the `remotename` option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer’s name. If that fails, pppd uses the null string as the peer’s name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted

pppd(1M)

using `crypt()` and checked against the secret again. If the `papcrypt` option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted `crypt(3C)` form.

If the `login` option is specified, the username and password are also checked against the system password database. This allows you to set up the `pap-secrets` file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the `login` option, the secret in `/etc/ppp/pap-secrets` would be "", which matches any password supplied by the peer. This makes having the same secret in two places unnecessary.

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, `pppd` closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To enable hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the `pap-secrets` file specifying the empty string for the client and password. Additional `pppd` options for a given authenticated peer may be specified by placing them at the end of the secrets entry, separated by two dashes (--). For example

```
peername servername secret ip-address -- novj
```

Routing

When IPCP negotiation is complete, `pppd` informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the `defaultroute` and/or `proxyarp` options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the `/etc/ppp/ip-up` script.

To add a default route through the remote host, use the `defaultroute` option.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. `proxyarp` instructs `pppd` to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, `pppd` creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

When the `demand` option is used, the interface IP addresses are already set at the time when IPCP comes up. If `pppd` cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

Scripts | pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable code files. pppd does not wait for the scripts to finish. The scripts are executed as `root` (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system's security. pppd runs the scripts with standard input, output and error redirected to `/dev/null`, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

<code>DEVICE</code>	Name of the serial tty device.
<code>IFNAME</code>	Name of the network interface.
<code>IPLOCAL</code>	IP address for the link's local end. This is set only when IPCP has started.
<code>IPREMOTE</code>	IP address for the link's remote end. This is set only when IPCP has started.
<code>PEERNAME</code>	Authenticated name of the peer. This is set only if the peer authenticates itself.
<code>SPEED</code>	Baud rate of the tty device.
<code>ORIG_UID</code>	Real user-id of user who invoked pppd.
<code>PPPLOGNAME</code>	Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

<code>CONNECT_TIME</code>	Number of seconds between the start of PPP negotiation and connection termination.
<code>BYTES_SENT</code>	Number of bytes sent at the level of the serial port during the connection.
<code>BYTES_RCVD</code>	Number of bytes received at the level of the serial port during the connection.
<code>LINKNAME</code>	Logical name of the link, set with the <code>linkname</code> option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

<code>/etc/ppp/auth-up</code>	Program or script executed after the remote system successfully authenticates itself. It is executed with the parameters <code>interface-name peer-name user-name tty-device speed</code> . Note that this script is not executed if the peer doesn't authenticate itself, for example when the <code>noauth</code> option is used.
<code>/etc/ppp/auth-down</code>	Program or script executed when the link goes down if <code>/etc/ppp/auth-up</code> was previously executed. It is

pppd(1M)

	executed in the same manner with the same parameters as <code>/etc/ppp/auth-up</code> .
<code>/etc/ppp/ip-up</code>	A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with the parameter <code>interface-name tty-device speed local-IP-address remote-IP-address ipparam</code> .
<code>/etc/ppp/ip-down</code>	A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the <code>/etc/ppp/ip-up</code> script. It is invoked in the same manner and with the same parameters as the <code>ip-up</code> script.
<code>/etc/ppp/ipv6-up</code>	Similar to <code>/etc/ppp/ip-up</code> , except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with the parameters <code>interface-name tty-device speed local-link-local-address remote-link-local-address ipparam</code> .
<code>/etc/ppp/ipv6-down</code>	Similar to <code>/etc/ppp/ip-down</code> , but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the <code>ipv6-up</code> script.

EXAMPLES

EXAMPLE 1 Using the `auth` Option

The following examples assume that the `/etc/ppp/options` file contains the `auth` option.

`pppd` is commonly used to dial out to an ISP. You can do this using the `pppd call isp` command where the `/etc/ppp/peers/isp` file is set up to contain a line similar to the following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, `chat(1M)` is used to dial the ISP's modem and process any logon sequence required. The `/etc/ppp/chat-isp` file is used by `chat` and could contain the following:

```
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
"" "at"
OK "at&f&d2&c1"
```

EXAMPLE 1 Using the auth Option (Continued)

```
OK "atdt2468135"
"name:" "^Umyuserid"
"word:" "\qmypassword"
"ispst" "\q^Uppp"
"--^Uppp--"
```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in `/etc/ppp/pap-secrets` or `/etc/ppp/chap-secrets`. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the `/etc/ppp/pap-secrets` or `/etc/ppp/chap-secrets` files:

```
joespc    server    "joe's secret"    joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is `/usr/bin/pppd` and whose home directory is `/etc/ppp`. If you run pppd this way, add the options to the `/etc/ppp/.ppprc` file.

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using `asynctest a0000`. If the path includes a telnet, escape ^] (`asynctest 200a0000`). If the path includes a `rlogin` command, add escape `ff` option to the options, because `rlogin` removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

EXIT STATUS

The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

- 0 pppd has detached or the connection was successfully established and terminated at the peer's request.
- 1 An immediately fatal error occurred. For example, an essential system call failed.
- 2 An error was detected in the options given. For example, two mutually exclusive options were used.

pppd(1M)

- 3 pppd is not `setuid-root` and the invoking user is not root.
- 4 The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
- 5 pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
- 6 The serial port could not be locked.
- 7 The serial port could not be opened.
- 8 The connect script failed and returned a non-zero exit status.
- 9 The command specified as the argument to the `pty` option could not be run.
- 10 The PPP negotiation failed because no network protocols were able to run.
- 11 The peer system failed or refused to authenticate itself.
- 12 The link was established successfully, but terminated because it was idle.
- 13 The link was established successfully, but terminated because the connect time limit was reached.
- 14 Callback was negotiated and an incoming call should arrive shortly.
- 15 The link was terminated because the peer is not responding to echo requests.
- 16 The link was terminated by the modem hanging up.
- 17 The PPP negotiation failed because serial loopback was detected.
- 18 The init script failed because a non-zero exit status was returned.
- 19 Authentication to the peer failed.

FILES	<code>/var/run/pppn.pid</code>	Process-ID for pppd process on ppp interface unit <i>n</i> .
	<code>/var/run/ppp-name.pid</code>	Process-ID for pppd process for logical link name (see the <code>linkname</code> option).
	<code>/etc/ppp/pap-secrets</code>	Username, passwords and IP addresses for PAP authentication. This file should be owned by root and not readable or writable by any other user, otherwise pppd will log a warning.
	<code>/etc/ppp/chap-secrets</code>	Names, secrets and IP addresses for all forms of CHAP authentication. The <code>/etc/ppp/pap-secrets</code> file should be owned by root should not readable or

	writable by any other user, otherwise, <code>pppd</code> will log a warning.
<code>/etc/ppp/options</code>	System default options for <code>pppd</code> , read before user default options or command-line options.
<code>\$HOME/.ppprc</code>	User default options, read before <code>/etc/ppp/options.ttyname</code> .
<code>/etc/ppp/options.ttyname</code>	System default options for the serial port in use; read after <code>\$HOME/.ppprc</code> . The <i>ttyname</i> component of this filename is formed when the initial <code>/dev/</code> is stripped from the port name (if present), and slashes (if any) are converted to dots.
<code>/etc/ppp/peers</code>	Directory with options files that may contain privileged options, (even if <code>pppd</code> was invoked by a user other than <code>root</code>). The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

NOTES

The following signals behave as follows when sent to pppd:

SIGINT, SIGTERM	Terminate the link, restore the serial device settings and exit.
SIGHUP	Terminate the link, restore the serial device settings and close the serial device. If the <code>persist</code> or <code>demand</code> option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately.
SIGUSR1	Toggles the state of the debug option.
SIGUSR2	Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

DIAGNOSTICS

Messages are sent to the syslog daemon using facility `LOG_DAEMON`. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.

NAME	pppoe – PPPoE chat utility
SYNOPSIS	<pre>pppoe [-omillsecs] [-smillsecs] [-v] device [service [[except]service... [only]]] pppoe [-omillsecs] [-v] -i [device]</pre>
DESCRIPTION	<p>The <code>pppoe</code> utility implements the client-side negotiation of PPPoE. It is intended to be used with the <code>pppd(1M)</code> <code>connect</code> option, in the same manner as the <code>chat(1M)</code> utility is used for asynchronous dial-up PPP.</p> <p>When given with the <code>-i</code> flag, <code>pppoe</code> sends out a broadcast query on the given interface named by the <code>device</code> parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.</p> <p>Otherwise, when given without the <code>-i</code> flag, <code>pppoe</code> does the full PPPoE client-side negotiation. The <code>device</code> parameter is the intended Ethernet interface, and must already be plumbed with <code>sppptun(1M)</code>. The optional <code>service</code> parameter specifies a particular service desired; other offered services will be ignored. The optional <code>server</code> parameter specifies a specific server desired. You can specify <code>server</code> as an Ethernet address in the usual <code>x:x:x:x:x</code> format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through <code>/etc/ethers</code> (or <code>NIS</code>), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword <code>except</code> before this string. This parameter can be specified more than once, and the first match is taken.</p> <p>If you specify the <code>server</code> parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword <code>only</code>.</p>
OPTIONS	<pre>-i Sends out broadcast query over interface specified by device. -o Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode. -s Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds). -v Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.</pre> <p>You normally do not need to adjust the parameters set with <code>-o</code> and <code>-s</code>. They are provided for coping with unusually slow servers.</p>
OPERANDS	<p>The following operands are supported:</p> <pre>device plumbed Ethernet interface</pre>

pppoe(1M)

server preferred server or, if you specify only, the specified server

service desired service; other available services are ignored

EXAMPLES **EXAMPLE 1** Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \  
connect "/usr/lib/inet/pppoe hme0" debug
```

Often, a command such as the preceding is specified in an `/etc/ppp/peers` file instead. For example, enter the following in `/etc/ppp/peers/myisp`:

```
sppptun  
plugin pppoe.so  
connect "/usr/lib/inet/pppoe hme0"  
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the `/etc/ppp/peers` files are considered privileged by `pppd`, you need not be root to invoke the preceding command.

EXAMPLE 2 Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name `isp`, but not to any Ethernet addresses starting with `40:0:1a`.

```
# /usr/lib/inet/pppoe hme0 internet except 40:0:1a:*:*:* isp only
```

Note that the `except 40:0:1a:*:*:*` filter must come before `isp`, because the filters are first-match.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

`/usr/lib/inet/pppoe`
executable command

`/dev/sppptun`
Solaris PPP tunneling device driver.

`/etc/ppp/connect-errors`
usual location of error output (see DIAGNOSTICS, below)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppd

SEE ALSO `pppd(1M)`, `sppptun(1M)`, `pppoed(1M)`

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

DIAGNOSTICS Error messages are written to standard error, which is normally redirected by `pppd` to `/etc/ppp/connect-errors`. The errors can also be redirected to `pppd`'s standard output by using the `updetach` option.

If you specify the `-v`, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the `updetach` or `nodetach` `pppd` option is helpful when using verbose mode.

matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client` list within a service is prepended to any list specified in the global context.

If no `client` options are given or if all options are specified with `except`, then all clients are permitted by default. If any `client` options without `except` are specified, then no clients are permitted by default.

The *client-list* is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through `/etc/ethers` or NIS, as defined by `/etc/nsswitch.conf`) or a hexadecimal Ethernet address in the format `x:x:x:x:x:x`. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, `40:0:1a:*:*:` matches Ethernet adapters from the manufacturer assigned block `40:0:1a`.

`debug`

Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to `syslog(3C)` using facility *daemon* (see the `log` option below). When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) detail level.

`device device-list`

Specify the devices on which the service is available. The *device-list* is a comma-separated list of logical device names (without the leading `/dev/`), such as `hme0`. This option is ignored if encountered in the per-device `/etc/ppp/pppoe.device` files.

`extra string`

Specifies extra options to `pppd(1M)`. It defaults to `"plugin pppoe.so directtty"` and usually does not need to be overridden.

`file path`

Suspends parsing of the current file, returns to global mode, and reads options from *path*. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

pppoed(1M)

	<p>The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes.</p> <p>This option can be used to revert to global mode at any point in an option file by specifying <code>file /dev/null</code>.</p>
<i>group name</i>	Specifies the group ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>log path</i>	Specifies an alternate debug logging file. Debug messages are sent to this file instead of <code>syslog</code> . The special name <code>syslog</code> is recognized to switch logging back to <code>syslog</code> . When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) log file.
<i>nodebug</i>	Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level.
<i>nowildcard</i>	Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests.
<i>path path</i>	Specifies the path to the <code>pppd</code> executable. Defaults to <code>/usr/bin/pppd</code> .
<i>pppd string</i>	Passes command-line arguments to <code>pppd</code> . It can be used to set the IP addresses or configure security for the session. The default value is the empty string.
<i>server string</i>	Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE".
<i>service name</i>	Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.

<i>user name</i>	Specifies the user ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>wildcard</i>	Specifies that the service should be included in responses to client queries that request "any" service (which is done by requesting a service name of length zero). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests. This is the default.

EXAMPLES **EXAMPLE 1** Configuring for Particular Services

In the `/etc/ppp/pppoe` file:

```
service internet
  device $DEV
  pppd "proxyarp 192.168.1.1:"
service debugging
  device hme0,$DEV
  pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
% /usr/lib/inet/pppoed DEV=1e0
```

The lines in `/etc/ppp/pppoe` and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface `1e0`, and offering only service "debugging" on interface `hme0`.

SIGNALS The `pppoed` daemon responds to the following signals:

SIGHUP	Causes <code>pppoed</code> to reparse the original command line and all configuration files, and close and reopen any log files.
SIGINT	Causes a snapshot of the state of the <code>pppoed</code> daemon to be written to <code>/tmp/pppoed.pid</code> (where <i>pid</i> is the decimal process ID of the daemon).

FILES	<code>/usr/lib/inet/pppoed</code>	executable command
	<code>/dev/sppptun</code>	Solaris PPP tunneling device driver
	<code>/etc/ppp/pppoe</code>	main configuration option file
	<code>/etc/ppp/pppoe.device</code>	per-device configuration option file
	<code>/etc/ppp/pppoe-errors</code>	location of output from <code>pppd</code> 's <code>stderr</code>
	<code>/etc/ppp/pppoe.if</code>	list of Ethernet interfaces to be plumbed at boot time
	<code>/tmp/pppoed.pid</code>	ASCII text file containing dumped <code>pppoed</code> state information

pppoed(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppd

SEE ALSO `pppd(1M)`, `pppoe(1M)`, `sppptun(1M)`

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

NOTES Because `pppd` is installed `setuid root`, this daemon need not be run as root. However, if it is not run as root, the `user` and `group` options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the `sppptun(1M)` utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `kill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

NAME	pppstats – print PPP statistics
SYNOPSIS	pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>] [<i>interface</i>]
DESCRIPTION	<p>The <code>pppstats</code> utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, <code>pppstats</code> defaults to <code>sppp0</code>. The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.</p> <p>The <code>pppstats</code> utility is part of Solaris PPP 4.0, an implementation of the Point-to-Point Protocol (PPP) that is based on the Australian National University PPP. For information on licensing terms, refer to the incorporated materials at <code>/var/sadm/pkg/SUNWpppdu/install/copyright</code>.</p>
OPTIONS	<p>The <code>pppstats</code> options are:</p> <ul style="list-style-type: none"> -a Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report. -c <i>count</i> Repeat the display <i>count</i> times. If this option is not specified, the default repeat count is 1 if the <code>-w</code> option is not specified, otherwise infinity. -r Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use. -v Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm. -w <i>wait</i> Pause <i>wait</i> seconds between each display. If this option is not specified, the default interval is five seconds. -z Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.
EXTENDED DESCRIPTION	<p>The following fields are printed on the input side when the <code>-z</code> option is not used:</p> <ul style="list-style-type: none"> IN Total number of bytes received by this interface. PACK Total number of packets received by this interface. VJCOMP Number of header-compressed TCP packets received by this interface. VJUNC Number of header-uncompressed TCP packets received by this interface. Not reported when the <code>-r</code> option is specified. VJERR Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the <code>-r</code> option is specified.

pppstats(1M)

VJTOSS	Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the <code>-v</code> option is specified.
NON-VJ	Total number of non-TCP packets received by this interface. Only reported when the <code>-v</code> option is specified.
RATIO	Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the <code>-r</code> option is specified.
UBYTE	Total number of bytes received, after decompression of compressed packets. Only reported when the <code>-r</code> option is specified.
The following fields are printed on the output side:	
OUT	Total number of bytes transmitted from this interface.
PACK	Total number of packets transmitted from this interface.
VJCOMP	Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.
VJUNC	Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the <code>-r</code> option is specified.
NON-VJ	Total number of non-TCP packets transmitted from this interface. Not reported when the <code>-r</code> option is specified.
VJSRCH	Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the <code>-v</code> option is specified.
VJMISS	Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the <code>-v</code> option is specified.
RATIO	Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the <code>-r</code> option is specified.
UBYTE	Total number of bytes to be transmitted before packet compression is applied. Only reported when the <code>-r</code> option is specified.
When the <code>-z</code> option is specified, <code>pppstats</code> displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:	
COMPRESSED BYTE	Number of bytes of compressed packets received.

COMPRESSED PACK	Number of compressed packets received.
INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.
INCOMPRESSIBLE PACK	Number of incompressible packets received.
COMP RATIO	Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).

The fields displayed on the output side are:

COMPRESSED BYTE	Number of bytes of compressed packets transmitted.
COMPRESSED PACK	Number of compressed packets transmitted.
INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
INCOMPRESSIBLE PACK	Number of incompressible packets transmitted.
COMP RATIO	Recent compression ratio for outgoing packets.

praudit(1M)

NAME praudit – print contents of an audit trail file

SYNOPSIS **praudit** [-lrs] [-ddel] [filename...]

DESCRIPTION praudit reads the listed *filenames* (or standard input, if no *filename* is specified) and interprets the data as audit trail records as defined in *audit.log(4)*. By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

OPTIONS

- l Prints one line per record. The record type and event fields are always converted to their short ASCII representation as is done for the -s option.
- r Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option and the -s option are exclusive. If both are used, a format usage error message is output.
- s Print records in their short form. All numeric fields are converted to ASCII and displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.
- ddel Use *del* as the field delimiter instead of the default delimiter, which is the comma. If *del* has special meaning for the shell, it must be quoted. The maximum size of a delimiter is four characters.

FILES /etc/security/audit_event
/etc/security/audit_class

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

NOTES The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See *bsmconv(1M)* for more information.

NAME	printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network
SYNOPSIS	<code>/usr/sadm/admin/bin/printmgr</code>
DESCRIPTION	<p>Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: NIS, NIS+, NIS+ with Federated Naming Service (FNS), and files. You must be logged in as superuser to use this tool.</p> <p>Using Solaris Printer Manager is the preferred method for managing printer access instead of <code>Admintool: Printers</code> because Solaris Print Manager centralizes printer information when it is used in a name service environment.</p> <p>Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized.</p> <p>Solaris Print Manager may be run on a remote system with the display sent to the local system. See <i>Managing Printing Services</i> in the <i>System Administration Guide: Basic Administration</i>, for instructions on setting the <code>DISPLAY</code> environment variable.</p> <p>Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the <code>lp</code> command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed.</p> <p>Help is available by clicking the Help button.</p>
USAGE	<p>Solaris Print Manager enables you to do the following tasks:</p> <p>Select a Name Service Select a name service for retrieving or changing printer information.</p> <p>Add Access to a Printer Add printer access on a printer client using Solaris Print Manager.</p> <p>Add an Attached Printer After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.</p> <p>Add a Network Printer After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.</p> <p>Modify Printer Properties After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes.</p>

printmgr(1M)

Delete a Printer

Delete access to a printer from the print client or delete a printer from the print server or from the name service environment.

NAME	prodreg – GUI viewer for Solaris Product Registry								
SYNOPSIS	<code>/usr/bin/prodreg</code> [<i>subcommand</i>]								
DESCRIPTION	The <code>prodreg</code> command is the viewer for the Solaris Product Registry (ProdReg), a system for maintaining records of the software products installed on a given Solaris system.								
OPERANDS	The following operands are supported: <table border="0"> <tr> <td style="padding-right: 20px;"><i>subcommand</i></td> <td>A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the <code>swing</code> subcommand.</td> </tr> </table>	<i>subcommand</i>	A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the <code>swing</code> subcommand.						
<i>subcommand</i>	A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the <code>swing</code> subcommand.								
USAGE	The following subcommands are supported: <table border="0"> <tr> <td style="padding-right: 20px;"><code>swing</code></td> <td>Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as <code>prodreg</code> with no arguments.</td> </tr> <tr> <td style="padding-right: 20px;"><code>awt</code></td> <td>Starts up the viewer using a Java AWT GUI.</td> </tr> <tr> <td style="padding-right: 20px;"><code>help</code></td> <td>Prints a usage message.</td> </tr> <tr> <td style="padding-right: 20px;"><code>version</code></td> <td>Prints the current version of the <code>prodreg</code> program.</td> </tr> </table>	<code>swing</code>	Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as <code>prodreg</code> with no arguments.	<code>awt</code>	Starts up the viewer using a Java AWT GUI.	<code>help</code>	Prints a usage message.	<code>version</code>	Prints the current version of the <code>prodreg</code> program.
<code>swing</code>	Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as <code>prodreg</code> with no arguments.								
<code>awt</code>	Starts up the viewer using a Java AWT GUI.								
<code>help</code>	Prints a usage message.								
<code>version</code>	Prints the current version of the <code>prodreg</code> program.								
ENVIRONMENT VARIABLES	The following environment variable affects the operation of <code>prodreg</code> : <table border="0"> <tr> <td style="padding-right: 20px;"><code>PKG_INSTALL_ROOT</code></td> <td>If present, defines the full path name of a directory to use as the system's <code>PKG_INSTALL_ROOT</code> path. All product and package information files are then looked for in the directory tree, starting with the specified <code>PKG_INSTALL_ROOT</code> path. If not present, the default system path of <code>"/</code> is used.</td> </tr> </table>	<code>PKG_INSTALL_ROOT</code>	If present, defines the full path name of a directory to use as the system's <code>PKG_INSTALL_ROOT</code> path. projadd(1M)

NAME	projadd – administer a new project on the system
SYNOPSIS	projadd [-c <i>comment</i>] [-U <i>user</i> [, <i>user...</i>]] [-G <i>group</i> [, <i>group...</i>]] [-p <i>projid</i> [<i>projid...</i>]] <i>project</i>
DESCRIPTION	projadd adds a new project entry to the /etc/project file. If the file's back end is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.
OPTIONS	<p>The following options are supported:</p> <p>-c <i>comment</i> Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name.</p> <p> Specify <i>comment</i> as a text string. <i>comment</i> cannot contain a colon (:) or NEWLINE.</p> <p>-G <i>group</i> Make <i>group</i> a member group of project.</p> <p> Specify <i>group</i> as a group ID or name.</p> <p>-o Enable duplication of a project ID.</p> <p>-p <i>projid</i> Set the project ID of the new project.</p> <p> Specify <i>projid</i> as a non-negative decimal integer below UID_MAX as defined in limits.h. <i>projid</i> defaults to the next available unique number above the highest number currently assigned. For example, if <i>projids</i> 100, 105, and 200 are assigned, the next default <i>projid</i> is 201. <i>projids</i> between 0-99 are reserved by SunOS.</p> <p>-U Add the existing users (as specified either by user ID or name), to member users of project.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>project</i> The name of the project to create. The <i>project</i> operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period ('.') is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. A warning message is displayed if these restrictions are not met.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>2 The command syntax was invalid. A usage message for projadd is displayed.</p> <p>3 An invalid argument was provided to an option.</p>

- 4 The *projid* given with the *-p* option is already in use.
 5 The project files contain an error. See *project(4)*.
 6 The project to be modified, group, or user does not exist.
 9 The project is already in use.
 10 Cannot update the */etc/project* file.

FILES */etc/project* System project file

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO *projects(1)*, *groupadd(1M)*, *groupdel(1M)*, *groupmod(1M)*, *grpchk(1M)*, *projdel(1M)*, *projmod(1M)*, *useradd(1M)*, *userdel(1M)*, *usermod(1M)*, *project(4)*, *attributes(5)*

NOTES In case of an error, *projadd* prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local */etc/project* file with additional entries, *projadd* cannot change information supplied by the network name service.

projdel(1M)

NAME projdel – delete a project from the system

SYNOPSIS **projdel** *project*

DESCRIPTION The **projdel** utility deletes a project from the system and makes the appropriate changes to the system file.

OPERANDS The following operands are supported:
project The name of the project to be deleted.

EXIT STATUS The following exit values are returned:
0 Successful completion.
project was deleted successfully.
1 An error occurred.
2 Invalid command line options

FILES /etc/project System project file

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO **projects(1)**, **groupadd(1M)**, **groupdel(1M)**, **groupmod(1M)**, **grpchk(1M)**, **logins(1M)**, **projadd(1M)**, **projmod(1M)**, **useradd(1M)**, **userdel(1M)**, **usermod(1M)**, **project(4)**, **attributes(5)**

DIAGNOSTICS In case of an error, **projdel** prints an error message and exits with a non-zero status.

NOTES **projdel** only deletes a project definition on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, **projdel** cannot change information supplied by the network name service.

NAME	projmod – modify a project’s information on the system
SYNOPSIS	projmod [-p <i>projid</i> [-o]] [-U <i>user</i> [, <i>user...</i>]] [-G <i>group</i> [, <i>group...</i>]] [-c <i>comment</i>] [-l <i>new_projectname</i>] <i>project</i>
DESCRIPTION	The <code>projmod</code> utility modifies a project’s definition on the system. <code>projmod</code> changes the definition of the specified project and makes the appropriate project-related system file and file system changes.
OPTIONS	<p>The following options are supported:</p> <p>-c <i>comment</i> Specify <i>comment</i> as a text string. Generally, <i>comment</i> contains a short description of the project. This information is stored in the project’s <code>/etc/project</code> entry.</p> <p>-G <i>group</i> [,<i>group...</i>] Specify a replacement list of member groups of the project.</p> <p>-l <i>new_projectname</i> Specify the new project name for the project. The <i>new_projectname</i> argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lowercase alphabetic character. A warning message is written if these restrictions are not met. A future Solaris release might refuse to accept login fields that do not meet these requirements. The <i>new_projectname</i> argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).</p> <p>-o This option allows the specified project ID to be duplicated (non-unique).</p> <p>-p <i>projid</i> Specify a new project ID for the project. It must be a non-negative decimal integer less than <code>MAXUID</code> as defined in <code>param.h</code>.</p> <p>-U <i>user</i> [, <i>user...</i>] Specify a replacement list of member users of the project.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>project</i> An existing project name to be modified.</p>
EXIT STATUS	<p>In case of an error, <code>projmod</code> prints an error message and exits with one of the following values:</p> <p>The following exit values are returned:</p> <p>0 Successful completion.</p>

projmod(1M)

- 2 The command syntax was invalid. A usage message for `projmod` is displayed.
- 3 An invalid argument was provided to an option.
- 4 The *projid* given with the `-p` option is already in use.
- 5 The project files contain an error. See `project(4)`.
- 6 The project to be modified, *group*, or *user* does not exist.
- 9 The project is already in use.
- 10 Cannot update the `/etc/project` file. Other update requests are implemented.

FILES	<code>/etc/group</code>	System file containing group definitions
	<code>/etc/project</code>	System project file
	<code>/etc/passwd</code>	System password file
	<code>/etc/shadow</code>	System file containing users' encrypted passwords and related information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `projadd(1M)`, `projdel(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `project(4)`, `attributes(5)`

NOTES The `projmod` utility modifies project definitions only in the local `/etc/project` file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, *projmod* cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.

NAME	prstat – report active process statistics
SYNOPSIS	prstat [-acJLmRtTv] [-C <i>psrsetlist</i>] [-j <i>projlist</i>] [-k <i>tasklist</i>] [-n <i>ntop</i> [, <i>nbottom</i>]] [-p <i>pidlist</i>] [-P <i>cpulist</i>] [-s <i>key</i> -S <i>key</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [<i>interval</i> [<i>count</i>]]
DESCRIPTION	<p>The <code>prstat</code> utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. <code>prstat</code> provides options to examine only processes matching specified PIDs, UIDs, CPU IDs, and processor set IDs.</p> <p>The <code>-j</code>, <code>-k</code>, <code>-C</code>, <code>-p</code>, <code>-P</code>, <code>-u</code>, and <code>-U</code> options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.</p> <p>If you do not specify an option, <code>prstat</code> examines all processes and reports statistics sorted by CPU usage.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-a</code> Report information about processes and users. In this mode <code>prstat</code> displays separate reports about processes and users at the same time. <code>-c</code> Print new reports below previous reports instead of overprinting them. <code>-C <i>psrsetlist</i></code> Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by <code>psrset(1M)</code>. <code>-j <i>projlist</i></code> Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See <code>project(4)</code>. <code>-J</code> Report information about processes and projects. In this mode <code>prstat</code> displays separate reports about processes and projects at the same time. <code>-k <i>tasklist</i></code> Report only processes or lwps whose task ID is in <i>tasklist</i>. <code>-L</code> Report statistics for each light-weight process (LWP). By default, <code>prstat</code> reports only the number of LWPs for each process. <code>-m</code> Report microstate process accounting information. In addition to all fields listed in <code>-v</code> mode, this mode also includes the percentage of time the process has spent

prstat(1M)

	processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).
-n <i>ntop</i> [, <i>nbottom</i>]	Restrict number of output lines. The <i>ntop</i> argument determines how many lines of process or lwp statistics are reported, and the <i>nbottom</i> argument determines how many lines of user, task, or projects statistics are reported if the -a, -t, -T, or -J options are specified. By default, <i>prstat</i> can display as many lines of output as will fit within a window or terminal.
-p <i>pidlist</i>	Report only processes whose process ID is in the given list.
-P <i>cpulist</i>	Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by <i>psrinfo</i> (1M).
-R	Put <i>prstat</i> in the real time scheduling class. When this option is used, <i>prstat</i> is given priority over time-sharing and interactive processes. This option is available only for superuser.
-s <i>key</i>	Sort output lines (that is, processes, lwps, or users) by <i>key</i> in descending order. Only one <i>key</i> can be used as an argument. There are five possible key values: cpu Sort by process CPU usage. This is the default. time Sort by process execution time. size Sort by size of process image. rss Sort by resident set size. pri Sort by process priority.
-S <i>key</i>	Sort output lines by <i>key</i> in ascending order. Possible <i>key</i> values are the same as for the -s option. See -s.
-t	Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images,

	total resident set size, total cpu time, and percentages of recent cpu time and system memory.
-T	Report information about processes and tasks. In this mode <code>prstat</code> displays separate reports about processes and tasks at the same time.
-u <i>euclidlist</i>	Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
-U <i>uidlist</i>	Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
-v	Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received.

OUTPUT The following list defines the column headings and the meanings of a `prstat` report:

PID	The process ID of the process.
USERNAME	The real user (login) name or real user ID.
SIZE	The total virtual memory size of the process, including all mapped files and devices, in kilobytes (K), megabytes (M), or gigabytes (G). The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G).
STATE	The state of the process: cpuN Process is running on CPU N. sleep Sleeping: process is waiting for an event to complete. run Runnable: process in on run queue. zombie Zombie state: process terminated and parent not waiting. stop Process is stopped.
PRI	The priority of the process. Larger numbers mean higher priority.
NICE	Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.

prstat(1M)

TIME	The cumulative execution time for the process.
CPU	The percentage of recent CPU time used by the process.
PROCESS	The name of the process (name of executed file).
LWPID	The lwp ID of the lwp being reported.
NLWP	The number of lwps in the process.

The following columns are displayed when the `-v` or `-m` option is specified

USR	The percentage of time the process has spent in user mode.
SYS	The percentage of time the process has spent in system mode.
TRP	The percentage of time the process has spent in processing system traps.
TFL	The percentage of time the process has spent processing text page faults.
DFL	The percentage of time the process has spent processing data page faults..
LCK	The percentage of time the process has spent waiting for user locks.
SLP	The percentage of time the process has spent sleeping
LAT	The percentage of time the process has spent in
VCX	The number of voluntary context switches.
ICX	The number of involuntary context switches.
SCL	The number of system calls.
SIG	The number of signals received.

Under the `-l` option, one line is printed for each lwp in the process and some reporting fields show the values for the lwp, not the process.

OPERANDS The following operands are supported:

<i>count</i>	Specifies the number of times that the statistics are repeated. By default, <code>prstat</code> reports statistics until a termination signal is received.
<i>interval</i>	Specifies the sampling interval in seconds; the default interval is 5 seconds.

EXAMPLES **EXAMPLE 1** Reporting the five most active superuser processes

The following command reports the five most active superuser processes running on CPU1 and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1
```

PID	USERNAME	SIZE	RSS	STATE	PRI	NICE	TIME	CPU	PROCESS/LWP
306	root	3024K	1448K	sleep	58	0	0:00.00	0.3%	sendmail/1
102	root	1600K	592K	sleep	59	0	0:00.00	0.1%	in.rdisc/1

EXAMPLE 1 Reporting the five most active superuser processes (Continued)

```

250  root      1000K  552K  sleep  58   0   0:00.00  0.0%  utmpd/1
288  root      1720K 1032K  sleep  58   0   0:00.00  0.0%  sac/1
  1   root       744K  168K  sleep  58   0   0:00.00  0.0%  init/1
TOTAL:          25, load averages:  0.05, 0.08, 0.12

```

EXAMPLE 2 Displaying verbose process usage information

The following command displays verbose process usage information about processes with lowest resident set sizes owned by users `root` and `john`.

```
example% prstat -S rss -n 5 -vc -u root,john
```

```

PID USERNAME  USR  SYS  TRP  TFL  DFL  LCK  SLP  LAT  VCX  ICX  SCL  SIG  PROCESS/LWP
  1  root      0.0  0.0  -   -   -   -  100  -   0   0   0   0  init/1
102  root      0.0  0.0  -   -   -   -  100  -   0   0   3   0  in.rdisc/1
250  root      0.0  0.0  -   -   -   -  100  -   0   0   0   0  utmpd/1
1185 john      0.0  0.0  -   -   -   -  100  -   0   0   0   0  csh/1
240  root      0.0  0.0  -   -   -   -  100  -   0   0   0   0  powerd/4
TOTAL:          71, load averages:  0.02, 0.04, 0.08

```

EXIT STATUS The following exit values are returned:

```

0          Successful completion.
1          An error occurred.

```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `proc(1)`, `psrinfo(1M)`, `psrset(1M)`, `sar(1M)`, `proc(4)`, `project(4)`, `attributes(5)`

NOTES The snap-shot of system usage displayed by `prstat` is true only for a split-second, and it may not be accurate by the time it is displayed. When the `-m` option is specified, `prstat` tries to turn on microstate accounting for each process; the original state is restored when `prstat` exits. See `proc(4)` for additional information about the microstate accounting facility.

prtconf(1M)

NAME	prtconf – print system configuration
SPARC	<code>/usr/sbin/prtconf [-V] [-F] [-x] [-vpPD]</code>
IA	<code>/usr/sbin/prtconf [-V] [-x] [-vpPD]</code>
DESCRIPTION	The <code>prtconf</code> command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-D For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.-F (SPARC only). Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, <code>prtconf</code> returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SPARCstation 1 is <code>cgthree</code> in SBus slot #3, the command returns: <code>/sbus@1, f80000000/cgthree@3, 0</code>. This option could be used to create a symlink for <code>/dev/fb</code> to the actual console device.-p Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on IA platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.-P Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.-v Specifies verbose mode.-V Displays platform-dependent PROM (on SPARC platforms) or booting system (on IA platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.-x Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel. <p>This flag overrides all other flags and must be used by itself.</p>

EXAMPLES | **EXAMPLE 1** Running prtconf on a SPARC Sun4/65 Series Machine

Running prtconf on a Sun4/65 series machine produces the following sample output:

```
example% prtconf
System Configuration: Sun Microsystems sun4c
Memory size: 16 Megabytes
System Peripherals (Software Nodes):
Sun 4_65
  options, instance #0
  zs, instance #0
  zs, instance #1
  fd (driver not attached)
  audio (driver not attached)
  sbus, instance #0
    dma, instance #0
    esp, instance #0
      sd (driver not attached)
      st (driver not attached)
      sd, instance #0
      sd, instance #1 (driver not attached)
      sd, instance #2 (driver not attached)
      sd, instance #3
      sd, instance #4 (driver not attached)
      sd, instance #5 (driver not attached)
      sd, instance #6 (driver not attached)
    le, instance #0
    cgsix (driver not attached)
  auxiliary-io (driver not attached)
  interrupt-enable (driver not attached)
  memory-error (driver not attached)
  counter-timer (driver not attached)
  eeprom (driver not attached)
  pseudo, instance #0
```

EXAMPLE 2 Running prtconf on an IA Machine

Running prtconf on an IA machine produces the following sample output:

```
example% prtconf
System Configuration: Sun Microsystems i86pc
Memory size: 32 Megabytes
System Peripherals (Software Nodes):
i86pc
  eisa, instance #0
    kd, instance #0
    ata, instance #0
      cmdk, instance #0
    aha, instance #0
      cmdk, instance #1 (driver not attached)
      cmdk, instance #2 (driver not attached)
      cmdk, instance #3 (driver not attached)
      cmdk, instance #4 (driver not attached)
      cmdk, instance #5 (driver not attached)
```

prtconf(1M)

EXAMPLE 2 Running prtconf on an IA Machine (Continued)

```
cmdk, instance #6 (driver not attached)
cmdk, instance #7
chanmux, instance #0
asy, instance #0
asy, instance #1
elx, instance #0
elx, instance #1 (driver not attached)
elx, instance #2 (driver not attached)
elx, instance #3 (driver not attached)
fdc, instance #0
fd, instance #0
fd, instance #1
options, instance #0
objmgr, instance #0
pseudo, instance #0
example%
```

EXIT STATUS The following exit values are returned:

0 No error occurred.

non-zero With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

Sun Hardware Platform Guide

SPARC Only openprom(7D)

NOTES The output of the prtconf command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The driver not attached message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached

prtconf(1M)

to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

prtdiag(1M)

NAME	prtdiag – display system diagnostic information				
SYNOPSIS	<code>/usr/platform/platform-name/sbin/prtdiag [-v] [-l]</code>				
DESCRIPTION	<p>prtdiag displays system configuration and diagnostic information on sun4u and sun4d systems.</p> <p>The diagnostic information lists any failed Field Replaceable Units (FRUs) in the system.</p> <p>The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases.</p> <p><i>platform-name</i> is the name of the platform implementation and can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>Note: prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the <code>/var/opt/SUNWssp/adm/\${SUNW_HOSTNAME}/messages</code> file on the System Service Processor (SSP) to obtain such information for this server.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-v</code> Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.<code>-l</code> Log output. If failures or errors exist in the system, output this information to <code>syslogd(1M)</code> only.				
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 No failures or errors are detected in the system.1 Failures or errors are detected in the system.2 An internal prtdiag error occurred, for example, out of memory.				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWkvm</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWkvm

NAME	prtfru – print FRUID-specific information about the FRUs on a system or domain				
SYNOPSIS	prtfru [-h] [-d] [-clx] prtfru [<i>container</i>]				
DESCRIPTION	<p>The <code>prtfru</code> utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.</p> <p><code>prtfru</code> without any arguments will print the FRU hierarchy and all of the FRUID container data. <code>prtfru</code> prints to stdout which may be redirected to a file.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -c Prints <i>only</i> the containers and their data. This option does not print the FRU tree hierarchy. -d Prints a DTD for the current registry to stdout. -h Displays a help message and exits. -l Prints <i>only</i> the FRU tree hierarchy. This option does not print the container data. -x Prints in XML format with a system identifier (SYSTEM) of <code>prtfrureg.dtd</code>. <p>Options <code>-c</code> and <code>-l</code> can be used together to obtain a list of the containers.</p>				
OPERANDS	<p>The following operand is supported:</p> <p><i>container</i> The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the <code>-l</code> option.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 All information was found and printed successfully. >0 An error has occurred. 				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWfruid</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWfruid

prtpicl(1M)

NAME prtpicl – print PICL tree

SYNOPSIS **prtpicl** [-c *picl_class*] [-v]

DESCRIPTION The `prtpicl` command prints the PICL tree maintained by the PICL daemon. The output of `prtpicl` includes the name and PICL class of the nodes.

OPTIONS The following options are supported:

- c *picl_class* Print only the nodes of the named PICL class.
- v Print in verbose mode. In verbose mode, `prtpicl` prints a list of properties and values for each node. Verbose mode is disabled by default.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

NAME	prtvtoC – report information about a disk geometry and partitioning				
SYNOPSIS	prtvtoC [-fhs] [-t <i>vfstab</i>] [-m <i>mnttab</i>] <i>device</i>				
DESCRIPTION	<p>The prtvtoC command allows the contents of the VTOC (volume table of contents) to be viewed. The command can be used only by the super-user.</p> <p>The <i>device</i> name can be the file name of a raw device in the form of /dev/rdisk/c?t?d?s2 or can be the file name of a block device in the form of /dev/dsk/c?t?d?s2.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -f Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions. -h Omit the headers from the normal output. -s Omit all headers but the column header from the normal output. -t <i>vfstab</i> Use <i>vfstab</i> as the list of filesystem defaults, in place of /etc/vfstab. -m <i>mnttab</i> Use <i>mnttab</i> as the list of mounted filesystems, in place of /etc/mnttab. 				
EXAMPLES	<p>EXAMPLE 1 The prtvtoC command.</p> <p>The command line entry and system response shown below are for a 424-megabyte hard disk:</p> <pre>example# prtvtoC /dev/rdisk/c0t3d0s2 * /dev/rdisk/c0t3d0s2 partition map * * Dimension: * 512 bytes/sector * 80 sectors/track * 9 tracks/cylinder * 720 sectors/cylinder * 2500 cylinders * 1151 accessible cylinders * * Flags: * 1: unmountable * 10: read-only *</pre> <p>The data in the Tag column above indicates the type of partition, as follows:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;"><i>Name</i></th> <th style="text-align: left;"><i>Number</i></th> </tr> </thead> <tbody> <tr> <td>UNASSIGNED</td> <td>0x00</td> </tr> </tbody> </table>	<i>Name</i>	<i>Number</i>	UNASSIGNED	0x00
<i>Name</i>	<i>Number</i>				
UNASSIGNED	0x00

NAME	psradm – change processor operational status
SYNOPSIS	<pre>psradm -f -i -n [-v] processor_id... psradm -a-f -i -n [-v]</pre>
DESCRIPTION	<p>The psradm utility changes the operational status of processors. The legal states for the processor are <i>on-line</i>, <i>off-line</i>, and <i>no-intr</i>.</p> <p>An <i>on-line</i> processor processes LWPs (lightweight processes) and may be interrupted by I/O devices in the system.</p> <p>An <i>off-line</i> processor does not process any LWPs. Usually, an <i>off-line</i> processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it may not be possible to disable interrupts for an <i>off-line</i> processor. Thus, the actual effect of being <i>off-line</i> may vary from machine to machine.</p> <p>A <i>no-intr</i> processor processes LWPs but is not interruptible by I/O devices.</p> <p>A processor may not be taken <i>off-line</i> if there are LWPs that are bound to the processor. On some architectures, it might not be possible to take certain processors <i>off-line</i> if, for example, the system depends on some resource provided by the processor.</p> <p>At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an <i>off-line</i> processor may be interruptible, it is possible to have an operational system with one processor <i>no-intr</i> and all other processors <i>off-line</i> but with one or more accepting interrupts.</p> <p>If any of the specified processors are powered off, psradm may power on one or more processors.</p> <p>Only superusers can use the psradm utility.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Perform the action on all processors, or as many as possible. -f Take the specified processors <i>off-line</i>. -i Set the specified processors <i>no-intr</i>. -n Bring the specified processors <i>on-line</i>. -v Output a message giving the results of each attempted operation.
OPERANDS	<p>The following operands are supported:</p> <p><i>processor_id</i> The processor ID of the processor to be set <i>on-line</i> or <i>off-line</i> or <i>no-intr</i>.</p> <p>Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for</p>

psradm(1M)

example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_ids* (for example, 13 5 78 9).

EXAMPLES

EXAMPLE 1 Examples of psradm.

The following example sets processors 2 and 3 off-line.

```
psradm -f 2 3
```

The following example sets processors 1 and 2 no-intr.

```
psradm -i 1 2
```

The following example sets all processors on-line.

```
psradm -a -n
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/etc/wtmpx records logging processor status changes

ATTRIBUTES

SEE ALSO

psrinfo(1M), psrset(1M), p_online(2), attributes(5)

DIAGNOSTICS

psradm: processor 4: Invalid argument
The specified processor does not exist in the configuration.

psradm: processor 3: Device busy
The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy
The specified processor could not be set no-intr because it is the last interruptible processor in the system, or or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy
The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm(1M)

psradm: processor 0: Not owner

The user does not have permission to change processor status.

psradm: processor 2: Operation not supported

The specified processor is powered off, and the platform does not support power on of individual processors.

psrinfo(1M)

NAME	psrinfo – displays information about processors
SYNOPSIS	psrinfo [-v] [<i>processor_id</i> ...] psrinfo -s <i>processor_id</i>
DESCRIPTION	<p>psrinfo displays information about processors.</p> <p>Without the <i>processor_id</i> operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), off-line, or powered off, and when that status last changed. Use the <i>processor_id</i> operand to display information about a specific processor. See OPERANDS.</p>
OPTIONS	<p>The following options are supported:</p> <p>-s <i>processor_id</i> Silent mode. Displays 1 if the specified processor is fully on-line, and 0 if the specified processor is non-interruptible, off-line, or powered off.</p> <p> Use silent mode when using psrinfo in shell scripts.</p> <p>-v Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>processor_id</i> The processor ID of the processor about which information is to be displayed.</p> <p> Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 13 5 78 9).</p>
EXAMPLES	<p>EXAMPLE 1 Displaying information about all configured processors in verbose mode.</p> <p>The following example displays information about all configured processors in verbose mode.</p> <pre>psrinfo -v</pre> <p>EXAMPLE 2 Determining if a processor is on-line.</p> <p>The following example uses psrinfo in a shell script to determine if a processor is on-line.</p> <pre>if ["`psrinfo -s 3 2> /dev/null`" -eq 1] then echo "processor 3 is up" fi</pre>

EXAMPLE 2 Determining if a processor is on-line. (Continued)

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `psradm(1M)`, `p_online(2)`, `processor_info(2)`, `attributes(5)`

DIAGNOSTICS `psrinfo: processor 9: Invalid argument`
The specified processor does not exist.

psrset(1M)

NAME	psrset – creation and management of processor sets
SYNOPSIS	<pre>psrset -a processor_set_id processor_id... psrset -b processor_set_id pid... psrset -c [processor_id...] psrset -d processor_set_id psrset -e processor_set_id command [argument(s)] psrset -f processor_set_id psrset [-i] [processor_set_id...] psrset -n processor_set_id psrset -p [processor_id...] psrset -q [pid...] psrset -r processor_id... psrset -u pid...</pre>
DESCRIPTION	<p>The <code>psrset</code> utility controls the management of processor sets. Processor sets allow the binding of processes to groups of processors, rather than just a single processor. There are two types of processor sets, those created by the user using the <code>psrset</code> command or the <code>pset_create(2)</code> system call, and those automatically created by the system. Processors assigned to user-created processor sets will run only LWPs that have been bound to that processor set, but system processor sets may run other LWPs as well.</p> <p>System-created processor sets will not always exist on a given machine. When they exist, they will generally represent particular characteristics of the underlying machine, such as groups of processors that can communicate more quickly with each other than with other processors in the system. These processor sets cannot be modified or removed, but processes may be bound to them.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Assigns the specified processors to the specified processor set. Processor sets automatically created by the system cannot have processors assigned to them. However, processors belonging to system processor sets may be assigned to user-created processor sets. This option is restricted to use by the super-user.-b Binds all the LWPs of the specified processes to the specified processor set. LWPs bound to a processor set will be restricted to run only on the processors in that set unless they require resources available only on another processor. Processes may only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

- Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.
- c** Creates a new processor set and displays the new processor set ID.
- If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors will be idle until LWPs are bound to the processor set. This option is restricted to use by the super-user.
- Only a limited number of processor sets may be active (created and not destroyed) at a given time. This limit will always be greater than the number of processors in the system. If the **-c** option is used when the maximum number of processor sets is already active, the command will fail.
- The following format will be used for the first line of output of the **-c** option when the `LC_MESSAGES` locale category specifies the "C" locale. In other locales, the strings `created`, `processor`, and `set` may be replaced with more appropriate strings corresponding to the locale.
- ```
"created processor set %d\n" processor set ID
```
- d** Removes the specified processor set, releasing all processors and processes associated with it.
- Processor sets automatically created by the system cannot be removed. This option is restricted to use by the super-user.
- e** Executes a command (with optional arguments) in the specified processor set.
- The command process and any child processes are executed only by processors in the processor set.
- The super-user may execute a command in any active processor set. Other users may only execute commands in system processor sets.
- f** Disables interrupts for all processors within the specified processor set.
- See `psradm(1M)`. If some processors in the set cannot have their interrupts disabled, the other processors will still have their interrupts disabled, and the command will report an error and return non-zero exit status. This option is restricted to use by the super-user.
- i** Displays a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.

## psrset(1M)

- n Enables interrupts for all processors within the specified processor set.  
See `psradm(1M)`. This option is restricted to use by the super-user.
- p Displays the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.
- q Displays the processor set bindings of the specified processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be shown. If no argument is given, the processor set bindings of all processes in the system is displayed.
- r Removes a list of processors from their current processor sets. Processors that are removed will return to either the system processor set to which they previously belonged, or to the general pool of processors if they did not belong to a system processor set. This option is restricted to use by the super-user.  
  
Processors with LWPs bound to them using `pbind(1M)` cannot be assigned to or removed from processor sets.
- u Removes the processor set bindings from all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.  
  
The super-user may bind or unbind any process to any active processor set. Other users may only bind or unbind processes to system processor sets. Furthermore, they may only bind or unbind processes for which they have permission to signal, that is, any process that has the same effective user ID as the user.

**OPERANDS** The following operands are supported:

- pid* Specify *pid* as a process ID.
- processor\_id* Specify *processor\_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor\_ids* (for example, 1 3 5 7 8 9).
- processor\_set\_id* Specify *processor\_set\_id* as a processor set ID.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- non-0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE  | ATTRIBUTE VALUE |
|-----------------|-----------------|
| Availability    | SUNWcsu         |
| Stability Level | Stable          |

**SEE ALSO** pbind(1M), psradm(1M), psrinfo(1M), processor\_bind(2), processor\_info(2), pset\_bind(2), pset\_create(2), pset\_info(2), sysconf(3C), attributes(5)

**DIAGNOSTICS**

psrset: cannot query pid 31: No such process  
The process specified did not exist or has exited.

psrset: cannot bind pid 31: Not owner  
The user does not have permission to bind the process.

psrset: cannot assign processor 4: Not owner  
The user does not have permission to assign the processor.

psrset: cannot assign processor 8: Invalid argument  
The specified processor is not on-line, or the specified processor does not exist.

psrset: cannot bind pid 67: Device busy  
An LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor.

psrset: cannot assign processor 7: Device busy  
The specified processor could not be added to the processor set. This may be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set.

psrset: cannot execute in processor set 8: Invalid argument  
The specified processor set does not exist.

psrset: cannot create processor set: Not enough space  
The maximum number of processor sets allowed in the system is already active.

## putdev(1M)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>              | putdev – edits device table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>          | <b>putdev</b> -a <i>alias</i> [ <i>attribute=value</i> [...] ]<br><b>putdev</b> -m <i>device attribute=value</i> [ <i>attribute = value</i> [...] ]<br><b>putdev</b> -d <i>device</i> [ <i>attribute</i> [...] ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>       | putdev adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.                                                             |
| <b>OPTIONS</b>           | The following options are supported:<br><br>-a            Add a device to the device table using the specified attributes. The device must be referenced by its <i>alias</i> .<br><br>-m            Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.<br><br>-d            Remove a device from the device table, when executed without the <i>attributes</i> argument. Used with the <i>attribute</i> argument, it deletes the given attribute specification for <i>device</i> from the table. |
| <b>OPERANDS</b>          | The following operands are supported:<br><br><i>alias</i> Designates the alias of the device to be added.<br><br><i>device</i> Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.<br><br><i>attribute</i> Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under <b>DEVICE ATTRIBUTES</b> except <i>alias</i> . This prevents an accidental modification or deletion of a device's alias from the table.<br><br><i>value</i> Designates the value to be assigned to a device's attribute.                                                                        |
| <b>DEVICE ATTRIBUTES</b> | The following list shows the standard device attributes, used by applications such as <b>ufsdump(1M)</b> and <b>ufsrestore(1M)</b> , which can be defined for a device. You are not limited to this list, you can define any attribute you like.<br><br><i>alias</i> The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore ( _ ), dollar sign (\$), hyphen (-), and period (.).                                                         |

|           |                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bdevice   | The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>cdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)     |
| capacity  | The capacity of the device or of the typical volume, if removable.                                                                                                                                                                                                                                                                                              |
| cdevice   | The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>bdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.) |
| cyl       | Used by the command specified in the <code>mkfscmd</code> attribute.                                                                                                                                                                                                                                                                                            |
| desc      | A description of any instance of a volume associated with this device (such as floppy diskette).                                                                                                                                                                                                                                                                |
| dpartlist | The list of disk partitions associated with this device. Used only if <code>type=disk</code> . The list should contain device aliases, each of which must have <code>type=dpart</code> .                                                                                                                                                                        |
| dparttype | The type of disk partition represented by this device. Used only if <code>type=dpart</code> . It should be either <code>fs</code> (for file system) or <code>dp</code> (for data partition).                                                                                                                                                                    |
| erasescmd | The command string that, when executed, erases the device.                                                                                                                                                                                                                                                                                                      |
| fmtcmd    | The command string that, when executed, formats the device.                                                                                                                                                                                                                                                                                                     |
| fsname    | The file system name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. This attribute is specified only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                                                                                                  |
| gap       | Used by the command specified in the <code>mkfscmd</code> attribute.                                                                                                                                                                                                                                                                                            |
| mkfscmd   | The command string that, when executed, places a file system on a previously formatted device.                                                                                                                                                                                                                                                                  |
| mountpt   | The default mount point to use for the device. Used only if the device is mountable. For disk partitions where <code>type=dpart</code> and <code>dparttype=fs</code> , this attribute should specify the location where the partition is normally mounted.                                                                                                      |
| nblocks   | The number of blocks in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                                                                                                                                                                                    |
| ninodes   | The number of inodes in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .                                                                                                                                                                                                                    |

## putdev(1M)

|          |                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| norewind | The name of the character special device node that allows access to the serial device without rewinding when the device is closed.                                                                 |
| pathname | Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).                                                                   |
| type     | A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.                                                     |
| volname  | The volume name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| volume   | A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.                                     |

**EXIT STATUS** The following exit values are returned:

|   |                                                                                                                                                                                                                                                                       |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Successful completion.                                                                                                                                                                                                                                                |
| 1 | Command syntax was incorrect, an invalid option was used, or an internal error occurred.                                                                                                                                                                              |
| 2 | The device table could not be opened for reading, or a new device table could not be created.                                                                                                                                                                         |
| 3 | If executed with the <code>-a</code> option, indicates that an entry in the device table with the alias <code>alias</code> already exists. If executed with the <code>-m</code> or <code>-d</code> options, indicates that no entry exists for device <i>device</i> . |
| 4 | Indicates that <code>-d</code> was requested and one or more of the specified attributes were not defined for the device.                                                                                                                                             |

**FILES** `/etc/device.tab`

| <b>NAME</b>        | putdgrp – edits device group table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>putdgrp</b> [-d] <i>dgroup</i> [ <i>device...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>putdgrp modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.</p> <p>When the command is invoked with only a <i>dgroup</i> specification, the command adds the specified group name to the device group table if it does not already exist. If the -d option is also used with only the <i>dgroup</i> specification, the command deletes the group from the table.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the -d option, the command deletes the device name(s) from the group definition.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification and the device group does not exist, it creates the group and adds the specified devices to that new group.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-d        Delete the group or, if used with <i>device</i>, delete the device from a group definition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>dgroup</i>    Specify a device group name.</p> <p><i>device</i>    Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0        Successful completion.</p> <p>1        Command syntax was incorrect, an invalid option was used, or an internal error occurred.</p> <p>2        Device group table could not be opened for reading or a new device group table could not be created.</p> <p>3        If executed with the -d option, indicates that an entry in the device group table for the device group <i>dgroup</i> does not exist and so cannot be deleted. Otherwise, indicates that the device group <i>dgroup</i> already exists and cannot be added.</p> <p>4        If executed with the -d option, indicates that the device group <i>dgroup</i> does not have as members one or more of the specified devices. Otherwise, indicates that the device group <i>dgroup</i> already has one or more of the specified devices as members.</p>                                                                                                                                                                                        |

## putdgrp(1M)

### EXAMPLES

**EXAMPLE 1** Adding a new device group.

The following example adds a new device group:

```
example# putdgrp floppies
```

**EXAMPLE 2** Adding a device to a device group.

The following example adds a device to a device group:

```
example# putdgrp floppies diskette2
```

**EXAMPLE 3** Deleting a device group.

The following example deletes a device group:

```
example# putdgrp -d floppies
```

**EXAMPLE 4** Deleting a device from a device group.

The following example deletes a device from a device group:

```
example# putdgrp -d floppies diskette2
```

### FILES

/etc/dgroup.tab

| <b>SYNOPSIS</b>    | <code>/usr/sbin/pwck [filename]</code><br><code>/usr/sbin/grpck [filename]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is <code>/etc/passwd</code>.</p> <p>grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than <code>NGROUPS_MAX</code> groups and that all login names appear in the password file. The default group file is <code>/etc/group</code>.</p> |                |                 |              |         |
| <b>FILES</b>       | <code>/etc/group</code><br><code>/etc/passwd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>NOTES</b>       | If no <code>filename</code> argument is given, <code>grpck</code> checks the local group file, <code>/etc/group</code> , and also makes sure that all login names encountered in the checked group file are known to the system <code>getpwent(3C)</code> routine. This means that the login names may be supplied by a network name service.                                                                                                                                                                                                                                                                      |                |                 |              |         |

pwconv(1M)

| <b>NAME</b>        | pwconv – installs and updates /etc/shadow with information from /etc/passwd                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>pwconv</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The pwconv command creates and updates /etc/shadow with information from /etc/passwd.</p> <p>pwconv relies on a special value of 'x' in the password field of /etc/passwd. This value of 'x' indicates that the password for the user is already in /etc/shadow and should not be modified.</p> <p>If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user's login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated.</p> <p>If the /etc/shadow file does exist, the following tasks will be performed:</p> <ul style="list-style-type: none"><li>Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file.</li><li>Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow.</li><li>Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow.</li></ul> <p>The pwconv command can only be used by the super-user.</p> |                |                 |              |         |

| <b>DESCRIPTION</b> | quot displays the number of blocks (1024 bytes) in the named <i>filesystem</i> currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-a       Generate a report for all mounted file systems.<br><br>-c       Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.<br><br>-f       Display count of number of files as well as space owned by each user. This option is incompatible with the -c and -v options.<br><br>-h       Estimate the number of blocks in the file. This does not account for files with holes in them.<br><br>-n       Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline<br><br>ncheck myfilesystem   sort +0n   quot -n myfilesystem<br><br>will produce a list of all files and their owners. This option is incompatible with all other options.<br><br>-v       In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days. |
| <b>OPERANDS</b>    | <i>filesystem</i> mount-point of the filesystem being checked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>USAGE</b>       | See <i>largefile(5)</i> for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EXIT STATUS</b> | 0       Successful operation.<br>32       Error condition (bad or missing argument, bad path, or other error).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>FILES</b>       | /etc/mnttab       mounted file systems<br>/etc/passwd       to get user names                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ATTRIBUTES</b>  | See <i>attributes(5)</i> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## quota(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | quota – display a user’s ufs file system disk quota and usage                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>quota</b> [-v] [ <i>username</i> ]                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>quota displays users’ ufs disk usage and limits. Only the super-user may use the optional <i>username</i> argument to view the limits of other users.</p> <p>quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.</p> <p><i>username</i> can be the numeric UID of a user.</p> |
| <b>OPTIONS</b>     | -v            Display user’s quota on all mounted file systems where quotas exist.                                                                                                                                                                                                                                                                                                                           |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>quota</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                          |
| <b>FILES</b>       | <code>/etc/mnttab</code> list of currently mounted filesystems                                                                                                                                                                                                                                                                                                                                               |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                 |

**SEE ALSO** `edquota(1M)`, `quotaon(1M)`, `quotacheck(1M)`, `repquota(1M)`, `rquotad(1M)`, `attributes(5)`, `largefile(5)`

**NOTES** `quota` will also display quotas for NFS mounted ufs-based file systems if the `rquotad` daemon is running. See `rquotad(1M)`.

`quota` may display entries for the same file system multiple times for multiple mount points. For example,

```
quota -v user1
```

may display identical quota information for `user1` at the mount points `/home/user1`, `/home/user2`, and `/home/user`, if all three mount points are mounted from the same file system with quotas turned on.

| <b>NAME</b>        | quotacheck – ufs file system quota consistency checker                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>quotacheck</b> [-fp] [-v] <i>filesystem...</i><br><b>quotacheck</b> -a [-fpv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>quotacheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.</p> <p><i>filesystem</i> is either a file system mount point or the block device on which the file system resides.</p> <p>quotacheck expects each file system to be checked to have a quota file named <i>quotas</i> in the root directory. If none is present, quotacheck will not check the file system.</p> <p>quotacheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotacheck is running.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-p        Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.</p> <p>-f        Force check on file systems with logging enabled. Use in combination with the -p option.</p> <p>-v        Indicate the calculated disk quotas for each user on a particular file system. quotacheck normally reports only those quotas modified.</p> <p>-a        Check the file systems which /etc/mnttab indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an rq entry in the mntopts field in /etc/vfstab.</p>                                                                                                                                                                         |                |                 |              |         |
| <b>USAGE</b>       | See <i>largefile(5)</i> for the description of the behavior of quotacheck when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>FILES</b>       | <p>/etc/mnttab        mounted file systems</p> <p>/etc/vfstab        list of default parameters for each file system</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

quotaon(1M)

**NAME** | quotaon, quotaoff – turn ufs file system quotas on and off

**SYNOPSIS** | **quotaon** [-v] *filesystem...*  
**quotaon** -a [-v]  
**quotaoff** [-v] *filesystem...*  
**quotaoff** -a [-v]

**DESCRIPTION** | quotaon turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named *quotas*, owned by root, must exist in the root directory of the file system. See *edquota(1M)* for details on how to modify the contents of this file.

quotaoff turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the *mntopts* field of the appropriate entries in */etc/mnttab* to indicate when quotas are on or off for each file system. If quotas are on, “quota” will be added to *mntopts*; if quotas are off, *mntopts* will be marked “noquota”.

*filesystem* must be either the mount point of a file system, or the block device on which the file system resides.

**quotaon** -a This option is normally used at boot time to enable quotas. It applies only to those file systems in */etc/vfstab* which have “rq” in the *mntopts* field, are currently mounted “rw”, and have a *quotas* file in the root directory.

-v Display a message for each file system after quotas are turned on.

**quotaoff** -a Force all file systems in */etc/mnttab* to have their quotas disabled.

-v Display a message for each file system affected.

**USAGE** | See *largefile(5)* for the description of the behavior of *quotaon* and *quotaoff* when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**FILES** | */etc/mnttab* mounted file systems  
*/etc/vfstab* list of default parameters for each file system

rdate(1M)

**NAME** rdate – set system date from a remote host

**SYNOPSIS** **rdate** *hostname*

**DESCRIPTION** rdate sets the local date and time from the *hostname* given as an argument. You must have the authorization `solaris.system.date` on the local system. Typically rdate can be inserted as part of a startup script.

**USAGE** The rdate command is IPv6-enabled. See `ip6(7P)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <code>/usr/sbin/reboot [-dlmq] [boot arguments]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>reboot</code> utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.</p> <p>Although <code>reboot</code> can be run by the super-user at any time, <code>shutdown(1M)</code> is normally used first to warn all users logged in of the impending loss of service. See <code>shutdown(1M)</code> for details.</p> <p>The <code>reboot</code> utility performs a <code>sync(1M)</code> operation on the disks, and then a multi-user reboot is initiated. See <code>init(1M)</code> for details.</p> <p>The <code>reboot</code> utility normally logs the reboot to the system log daemon, <code>syslogd(1M)</code>, and places a shutdown record in the login accounting file <code>/var/adm/wtmpx</code>. These actions are inhibited if the <code>-n</code> or <code>-q</code> options are present.</p> <p>Normally, the system will reboot itself at power-up or after crashes.</p> |
| <b>OPTIONS</b>     | <p><code>-d</code> Force a system crash dump before rebooting. See <code>dumpadm(1M)</code> for information on configuring system crash dumps.</p> <p><code>-l</code> Suppress sending a message to the system log daemon, <code>syslogd(1M)</code> about who executed <code>reboot</code>.</p> <p><code>-n</code> Avoid the <code>sync(1M)</code> operation. Use of this option can cause file system damage.</p> <p><code>-q</code> Quick. Reboot quickly and ungracefully, without shutting down running processes first.</p> <p><i>bootarguments</i> These arguments are accepted for compatibility, and are passed unchanged to the <code>uadmin(2)</code> function.</p>                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Example of the <code>reboot</code> utility.</p> <p>In the example below, the delimiter ‘<code>--</code>’ (two hyphens) must be used to separate the options of <code>reboot</code> from the arguments of <code>boot(1M)</code>.</p> <pre>example# reboot -dl -- -rv</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>FILES</b>       | <code>/var/adm/wtmpx</code> login accounting file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>SYNOPSIS</b>    | <b>rem_drv</b> [-b <i>basedir</i> ] <i>device_driver</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>rem_drv</code> command informs the system that the device driver <i>device_driver</i> is no longer valid. If possible, <code>rem_drv</code> unloads <i>device_driver</i> from memory. Entries for the device in the <code>/devices</code> namespace are removed. <code>rem_drv</code> also updates the system driver configuration files.</p> <p>If <code>rem_drv</code> has been executed, the next time the system is rebooted it will automatically perform a reconfiguration boot (see <code>kernel(1M)</code>).</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p><b>-b <i>basedir</i></b> Sets the path to the root directory of the diskless client. Used on the server to execute <code>rem_drv</code> for a client. The client machine must be rebooted to unload the driver.</p>                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of <code>rem_drv</code>.</p> <p>The following example removes the <code>sd</code> driver from use:</p> <pre>example% rem_drv sd</pre> <p>The next example removes the driver from the <code>sun1</code> diskless client. The driver will not be uninstalled nor unloaded until the client machine is rebooted.</p> <pre>example% rem_drv -b /export/root/sun1 sd</pre>                                                                                                                                   |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |

| <b>NAME</b>        | removef – remove a file from software database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>removef</b> [ [-M] -R <i>root_path</i> ] [-V <i>fs_file</i> ] <i>pkginst path...</i><br><b>removef</b> [ [-M] -R <i>root_path</i> ] [-V <i>fs_file</i> ] -f <i>pkginst</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | -f                    After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.<br>-M                    Instruct removef not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.<br>-R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i> ).<br>-V <i>fs_file</i> Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable. |
| <b>OPERANDS</b>    | <i>pkginst</i> The package instance from which the pathname is being removed.<br><i>path</i> The pathname to be removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> The removef command.<br>The following shows the use of removef in an optional pre-install script:<br><pre>echo            "The following files are no longer part of this package                 and are being removed." removef \$PKGINST /dev/xt[0-9][0-9][0-9]   while read pathname do     echo "\$pathname"     rm -f \$pathname done removef -f \$PKGINST    exit 2</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## repquota(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | repquota – summarize quotas for a ufs file system                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>repquota</b> [-v] <i>filesystem...</i><br><b>repquota</b> -a [-v]                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M).</p> <p>The <i>filesystem</i> must have the file <i>quotas</i> in its root directory.</p> <p>Only the super-user may view quotas which are not their own.</p> |
| <b>OPTIONS</b>     | -a        Report on all mounted ufs file systems that have <i>rq</i> in the <i>mntopts</i> field of the <i>/etc/vfstab</i> file.<br>-v        Report quotas for all users, even those who do not consume resources.                                                                                                                                                                                |
| <b>USAGE</b>       | See <i>largefile(5)</i> for the description of the behavior of <i>repquota</i> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                         |
| <b>ATTRIBUTES</b>  | See <i>attributes(5)</i> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | re-preinstall – installs the JumpStart software on a system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>cdrom-mnt-pt/Solaris_2.6/Tools/Boot/usr/sbin/install.d/re-preinstall</code><br><code>[-m Solaris_boot_dir] [-k platform_name] target-slice</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>re-preinstall installs the JumpStart software (Preinstall Boot Image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. All new SPARC systems have the JumpStart software already preinstalled.</p> <p>There are two ways to use the re-preinstall command. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.)</p> <p>You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). Once you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.)</p> <p>re-preinstall creates a standard file system on the specified <i>target-slice</i> (usually slice 0), and re-preinstall makes sure there is enough space on the <i>target-slice</i> for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message:</p> <pre>re-preinstall: target-slice too small xx Megabytes required</pre> <p>You can use the format(1M) command to create sufficient space on the <i>target-slice</i> for the JumpStart software.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-k platform_name</code> Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the uname(1) command (-i option) to determine a system's platform name.)</p> <p><code>-m Solaris_boot_dir</code> Absolute path to the Solaris_2.6/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is /cdrom/Solaris_2.6/Tools/Boot, which is where the Solaris CD is mounted in single-user mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>target-slice</i> Device name of the disk slice where the JumpStart software will be installed (usually slice 0). For example, c0t3d0s0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## re-preinstall(1M)

### EXAMPLES

**EXAMPLE 1** Installing the Jumpstart software.

The following procedure installs the Jumpstart software on a system's own default boot disk:

1. From the "ok" prompt, boot the system from the Solaris CD (local or remote) in single-user mode:

```
ok boot cdrom -s
```

2. With the `re-preinstall` command, install the JumpStart software on the system's default boot disk, which is a slice on the disk (usually slice 0) where the system automatically boots from. (The system's default boot disk is probably where the current root (/) file system is located, which can be determined with the `format(1M)` command.)

For example, the following command installs the JumpStart software on the system's default boot disk, `c0t3d0s0`:

```
example# /cdrom/Solaris_2.6/Tools/Boot/usr/sbin/install.d\
/re-preinstall c0t3d0s0
```

The following procedure installs the JumpStart software on a system's attached disk (non-boot disk):

1. Mount the Solaris CD if `vold(1M)` is not running or CD is not mounted.
2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.
3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run `re-preinstall` with the `-m Solaris_boot_dir` option if the Solaris CD is not mounted on `/cdrom`.

For example, the following command installs the JumpStart software on the system's attached disk for a system with a Sun4c kernel architecture, and it uses the Solaris CD mounted with `vold(1M)`:

```
example# /cdrom/cdrom0/s0/Solaris_2.6/Tools/Boot/usr/bin\
/install.d/re-preinstall\
-m /cdrom/cdrom0/s0/Solaris_2.6/Tools/Boot\
-k sun4c c0t2d0s0
```

### EXIT STATUS

The following exit values are returned:

- |   |                        |
|---|------------------------|
| 0 | Successful completion. |

| <b>SYNOPSIS</b>                           | <code>/usr/sbin/rmmount [-D]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                |                              |                                                       |                                  |                      |                                     |                        |                            |                                                       |                                 |                      |                                           |                                                   |                                   |                        |
| <b>DESCRIPTION</b>                        | <p>The rmmount utility is a removable media mounter that is executed by Volume Management whenever a CD-ROM or floppy is inserted. The Volume Management daemon, <code>vold(1M)</code>, manages CD-ROM and floppy devices. rmmount can also be called by using <code>volrmmount(1)</code>.</p> <p>Upon insertion, rmmount determines what type of file system (if any) is on the media. If a file system is present, rmmount mounts the file system in one of the following locations:</p> <table><thead><tr><th>Mount Location</th><th>State of Media</th></tr></thead><tbody><tr><td><code>/floppy/floppy0</code></td><td>symbolic link to mounted floppy in local floppy drive</td></tr><tr><td><code>/floppy/floppy_name</code></td><td>mounted named floppy</td></tr><tr><td><code>/floppy/unnamed_floppy</code></td><td>mounted unnamed floppy</td></tr><tr><td><code>/cdrom/cdrom0</code></td><td>symbolic link to mounted CD-ROM in local CD-ROM drive</td></tr><tr><td><code>/cdrom/CD-ROM_name</code></td><td>mounted named CD-ROM</td></tr><tr><td><code>/cdrom/CD-ROM_name/partition</code></td><td>mounted named CD-ROM with partitioned file system</td></tr><tr><td><code>/cdrom/unnamed_cdrom</code></td><td>mounted unnamed CD-ROM</td></tr></tbody></table> <p>If the media is read-only (either CD-ROM or floppy with write-protect tab set), the file system is mounted read-only.</p> <p>If a file system is not identified, rmmount does not mount a file system. See the <i>System Administration Guide, Volume 1</i> for more information on the location of CD-ROM and floppy media without file systems. Also see <code>volfs(7FS)</code>.</p> <p>If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” <code>fsck -p</code> (see <code>fsck(1M)</code>) is run in an attempt to clean it. If <code>fsck</code> fails, the file system is mounted read-only.</p> <p>After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, <code>/etc/rmmount.conf</code>.</p> <p>Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.</p> | Mount Location | State of Media | <code>/floppy/floppy0</code> | symbolic link to mounted floppy in local floppy drive | <code>/floppy/floppy_name</code> | mounted named floppy | <code>/floppy/unnamed_floppy</code> | mounted unnamed floppy | <code>/cdrom/cdrom0</code> | symbolic link to mounted CD-ROM in local CD-ROM drive | <code>/cdrom/CD-ROM_name</code> | mounted named CD-ROM | <code>/cdrom/CD-ROM_name/partition</code> | mounted named CD-ROM with partitioned file system | <code>/cdrom/unnamed_cdrom</code> | mounted unnamed CD-ROM |

In order to execute an action, rmmount performs a `dlopen(3DL)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by rmmount are always mounted with the `nosuid` flag set, thereby disabling set-uid programs and access to block or character devices in that file system. Upon ejection, rmmount unmounts mounted file systems and executes actions associated with the media type. If a file system is "busy" (that is, it contains the current working directory of a live process), the ejection will fail.

**OPTIONS** -D Turn on the debugging output from the rmmount `dprintf` calls.

**FILES** `/etc/rmmount.conf` removable media mounter configuration file.

`/usr/lib/rmmount/*.so.1` shared objects used by rmmount.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWvolu        |

| <b>DESCRIPTION</b>                   | <p>rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an <code>rexec(3SOCKET)</code> or <code>rcmd(3SOCKET)</code> call.</p> <p>The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:</p> <p><i>Anumber</i>\n<br/>where <i>number</i> is an ASCII representation of a decimal number.</p> <p>Unsuccessful commands are responded to with:</p> <p><i>Error-number</i>\n<i>error-message</i>\n<br/>where <i>error-number</i> is one of the possible error numbers described in <code>intro(3)</code>, and <i>error-message</i> is the corresponding error string as printed from a call to <code>perror(3C)</code>.</p> <p>The protocol consists of the following commands:</p> <table><tr><td><i>S</i>\n</td><td>Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).</td></tr><tr><td><i>Cdevice</i>\n</td><td>Close the currently open device. The <i>device</i> specified is ignored.</td></tr><tr><td><i>Ioperation</i>\n<i>count</i>\n</td><td>Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.</td></tr><tr><td><i>Loffset</i>\n<i>nwhence</i>\n</td><td>Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call.</td></tr><tr><td><i>Odevice</i>\n<i>mode</i>\n</td><td>Open the specified <i>device</i> using the indicated <i>mode</i>. <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code>. If a device is already open, it is closed before a new open is performed.</td></tr><tr><td><i>Rcount</i>\n</td><td>Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read(9E)</code> and responds with <i>Acount-read</i>\n if the read was successful; otherwise an</td></tr></table> | <i>S</i> \n | Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary). | <i>Cdevice</i> \n | Close the currently open device. The <i>device</i> specified is ignored. | <i>Ioperation</i> \n <i>count</i> \n | Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter. | <i>Loffset</i> \n <i>nwhence</i> \n | Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call. | <i>Odevice</i> \n <i>mode</i> \n | Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code> . If a device is already open, it is closed before a new open is performed. | <i>Rcount</i> \n | Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read(9E)</code> and responds with <i>Acount-read</i> \n if the read was successful; otherwise an |
| <i>S</i> \n                          | Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                                                                                                                                                                                                                              |                   |                                                                          |                                      |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                  |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |

| <i>Ioperation</i> \n <i>count</i> \n | Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                                                                                                                                                                                                              |                   |                                                                          |                                      |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                  |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |
| <i>Loffset</i> \n <i>nwhence</i> \n  | Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |                                                                                                                                                                                                                              |                   |                                                                          |                                      |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                  |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |
| <i>Odevice</i> \n <i>mode</i> \n     | Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code> . If a device is already open, it is closed before a new open is performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |             |                                                                                                                                                                                                                              |                   |                                                                          |                                      |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                  |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |
| <i>Rcount</i> \n                     | Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read(9E)</code> and responds with <i>Acount-read</i> \n if the read was successful; otherwise an                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                                                                                                                                                                                                                              |                   |                                                                          |                                      |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                  |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |

rmt(1M)

error in standard format is returned. If the read was successful, the data read is sent.

*wcount*\n

Write data onto the open device. *rmt* reads *count* bytes from the connection, aborting if a premature EOF is encountered. The response value is returned from the *write(9E)* call.

Any other command causes *rmt* to exit.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *ufsdump(1M)*, *ufsrestore(1M)*, *intro(3)*, *ioctl(2)*, *lseek(2)*, *perror(3C)*, *rcmd(3SOCKET)*, *rexec(3SOCKET)*, *attributes(5)*, *mtio(7I)*, *open(9E)*, *read(9E)*, *write(9E)*

**DIAGNOSTICS** All responses are of the form described above.

**BUGS** Do not use this for a remote file access protocol.

| <b>DESCRIPTION</b> | <p>roleadd adds a role entry to the <code>/etc/passwd</code> and <code>/etc/shadow</code> and <code>/etc/user_attr</code> files. The <code>-A</code> and <code>-P</code> options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles.</p> <p>roleadd also creates supplementary group memberships for the role (<code>-G</code> option) and creates the home directory (<code>-m</code> option) for the role if requested. The new role account remains locked until the <code>passwd(1)</code> command is executed.</p> <p>Specifying <code>roleadd -D</code> with the <code>-g</code>, <code>-b</code>, <code>-f</code>, or <code>-e</code> option (or any combination of these option) sets the default values for the respective fields. See the <code>-D</code> option. Subsequent <code>roleadd</code> commands without the <code>-D</code> option use these arguments.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.</p> <p>The <code>role</code> (<code>role</code>) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (<code>.</code>), underscore (<code>_</code>), and hyphen (<code>-</code>). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept role fields that do not meet these requirements.</p> <p>The <code>role</code> field must contain at least one character and must not contain a colon (<code>:</code>) or a newline (<code>\n</code>).</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-b <i>base_dir</i></code> The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist.</li><li><code>-c <i>comment</i></code> Any text string. It is generally a short description of the role. This information is stored in the role's <code>/etc/passwd</code> entry.</li><li><code>-d <i>dir</i></code> The home directory of the new role. It defaults to <code>base_dir/account_name</code>, where <i>base_dir</i> is the base directory for new login home directories and <i>account_name</i> is the new role name.</li><li><code>-D</code> Display the default values for <i>group</i>, <i>base_dir</i>, <i>skel_dir</i>, <i>shell</i>, <i>inactive</i>, and <i>expire</i>. When used with the <code>-g</code>, <code>-b</code>, or <code>-f</code> options, the <code>-D</code> option sets the default values for the specified fields. The default values are:</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                    |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                    | expire   | Null                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                    | auths    | Null                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                    | profiles | Null                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -e <i>expire</i>   |          | Specify the expiration date for a role. After this date, no user will be able to access this role. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code> . See <code>getdate(3C)</code> .<br><br>If the date format that you choose includes spaces, it must be quoted. For example, you can enter <code>10/6/90</code> or <code>"October 6, 1990"</code> . A null value ( <code>" "</code> ) defeats the status of the expired date. This option is useful for creating temporary roles. |
| -f <i>inactive</i> |          | The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.                                                                                                                                                                                                                                                                                                                                                                                                 |
| -g <i>group</i>    |          | An existing group's integer ID or character-string name. Without the <code>-D</code> option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking <code>roleadd -D -g group</code> .                                                                                                                                                                                                                                                                                                     |
| -G <i>group</i>    |          | An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between <i>group</i> with the <code>-g</code> and <code>-G</code> options are ignored. No more than <code>NGROUPS_MAX</code> groups can be specified.                                                                                                                                                                                                                                                                                    |
| -k <i>skel_dir</i> |          | A directory that contains skeleton information (such as <code>.profile</code> ) that can be copied into a new role's home directory. This directory must already exist. The system provides the <code>/etc/skel</code> directory that can be used for this purpose.                                                                                                                                                                                                                                                                                                    |
| -m                 |          | Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by <i>group</i> , where <i>group</i> is the role's primary group.                                                                                                                                                                                                                                                                                                                                                |
| -o                 |          | This option allows a UID to be duplicated (non-unique).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -s <i>shell</i>    |          | Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use <code>/bin/sh</code> as the default. The value of <i>shell</i> must be a valid executable file.                                                                                                                                                                                                                                                                                                                                                |

## roleadd(1M)

**-u *uid***      The UID of the new role. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved for possible use in future applications.)

**FILES**      `/etc/datemsk`  
`/etc/passwd`  
`/etc/shadow`  
`/etc/group`  
`/etc/skel`  
`/usr/include/limits.h`  
`/etc/user_attr`

**ATTRIBUTES**      See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**      `passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `pwck(1M)`, `userdel(1M)`, `usermod(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

**DIAGNOSTICS**      In case of an error, `roleadd` prints an error message and exits with a non-zero status.

The following indicates that `login` specified is already in use:

UX: `roleadd: ERROR: login is already in use. Choose another.`

The following indicates that the `uid` specified with the `-u` option is not unique:

UX: `roleadd: ERROR: uid uid is already in use. Choose another.`

The following indicates that the `group` specified with the `-g` option is already in use:

UX: `roleadd: ERROR: group group does not exist. Choose another.`

The following indicates that the `uid` specified with the `-u` option is in the range of reserved UIDs (from 0-99):

UX: `roleadd: WARNING: uid uid is reserved.`

The following indicates that the *uid* specified with the *-u* option exceeds MAXUID as defined in `<sys/param.h>`:

```
UX: roleadd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:

```
UX: roleadd: ERROR: Cannot update system files - login cannot be created.
```

**NOTES** If a network nameservice such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `roleadd` cannot change information supplied by the network nameservice.

roledel(1M)

**NAME** roledel – delete a role’s login from the system

**SYNOPSIS** **roledel** [-r] *role*

**DESCRIPTION** The roledel utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. roledel also removes the role from each user’s list of assumable roles.

**OPTIONS** The following options are supported:

-r Remove the role’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

**OPERANDS** The following operands are supported:

*role* An existing role name to be deleted.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

2 Invalid command syntax. A usage message for the roledel command is displayed.

6 The account to be removed does not exist.

8 The account to be removed is in use.

10 Cannot update the /etc/group or /etc/user\_attr file but the login is removed from the /etc/passwd file.

12 Cannot remove or otherwise modify the home directory.

**FILES**

|                |                                                                           |
|----------------|---------------------------------------------------------------------------|
| /etc/passwd    | system password file                                                      |
| /etc/shadow    | system file containing roles’ encrypted passwords and related information |
| /etc/group     | system file containing group definitions                                  |
| /etc/user_attr | system file containing additional role attributes                         |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), roleadd(1M), rolemod(1M),

roledel(1M)

useradd(1M), userdel(1M), usermod(1M), passwd(4), prof\_attr(4),  
user\_attr(4), attributes(5)

**NOTES** The roledel utility only deletes an account definition that is in the local /etc/group, /etc/passwd, /etc/shadow, and /etc/user\_attr file. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, roledel cannot change information supplied by the network name service.

| <b>DESCRIPTION</b> | <p>The <b>rolemod</b> utility modifies a role’s login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-A <i>authorization</i> One or more comma separated authorizations as defined in <code>auth_attr(4)</code>. Only role with <code>grant</code> rights to the <code>authorization</code> can assign it to an account. This replaces any existing authorization setting.</li><li>-c <i>comment</i> Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry.</li><li>-d <i>dir</i> Specify the new home directory of the role. It defaults to <code>base_dir/login</code>, where <i>base_dir</i> is the base directory for new login home directories, and <code>login</code> is the new login.</li><li>-e <i>expire</i> Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>.<br/><br/>For example, you may enter <code>10/6/90</code> or <code>October 6, 1990</code>. A value of <code>''</code> defeats the status of the expired date.</li><li>-f <i>inactive</i> Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.</li><li>-g <i>group</i> Specify an existing group’s integer ID or character-string name. It redefines the role’s primary group membership.</li><li>-G <i>group</i> Specify an existing group’s integer "ID" or character string name. It redefines the role’s supplementary</li></ul> |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | group membership. Duplicates between <i>group</i> with the <i>-g</i> and <i>-G</i> options are ignored. No more than <code>NGROUPS_UMAX</code> groups may be specified as defined in <code>&lt;param.h&gt;</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>-l new_logname</i> | Specify the new login name for the role. The <i>new_logname</i> argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period ( <code>.</code> ), underline ( <code>_</code> ), and hyphen ( <code>-</code> ). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The <i>new_logname</i> argument must contain at least one character and must not contain a colon ( <code>:</code> ) or NEWLINE ( <code>\n</code> ). |
| <i>-m</i>             | Move the role's home directory to the new directory specified with the <i>-d</i> option. If the directory already exists, it must have permissions read/write/execute by <i>group</i> , where <i>group</i> is the role's primary group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>-o</i>             | This option allows the specified UID to be duplicated (non-unique).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>-P profile</i>     | One or more comma-separated execution profiles defined in <code>auth_attr(4)</code> . This replaces any existing profile setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>-s shell</i>       | Specify the full pathname of the program that is used as the role's shell on login. The value of <i>shell</i> must be a valid executable file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>-u uid</i>         | Specify a new UID for the role. It must be a non-negative decimal integer less than <code>MAXUID</code> as defined in <code>&lt;param.h&gt;</code> . The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using <code>chown(1M)</code> .                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPERANDS</b>       | The following operands are supported:<br><i>login</i> An existing login name to be modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXIT STATUS</b>    | In case of an error, <code>rolemod</code> prints an error message and exits with one of the following values:<br>2 The command syntax was invalid. A usage message for the <code>rolemod</code> command is displayed.<br>3 An invalid argument was provided to an option.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## rolemod(1M)

- 4 The *uid* given with the *-u* option is already in use.
- 5 The password files contain an error. *pwconv(1M)* can be used to correct possible errors. See *passwd(4)*.
- 6 The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8 The login to be modified is in use.
- 9 The *new\_logname* is already in use.
- 10 Cannot update the */etc/group* or */etc/user\_attr* file. Other update requests will be implemented.
- 11 Insufficient space to move the home directory (*-m* option). Other update requests will be implemented.
- 12 Unable to complete the move of the home directory to the new home directory.

| <b>NAME</b>        | route – manually manipulate the routing tables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre> <b>route</b> [-fnvq] <i>command</i> [ [<i>modifiers</i>] <i>args</i>] <b>route</b> [-fnvq] add   delete [<i>modifiers</i>] <i>destination gateway</i> [<i>args</i>] <b>route</b> [-fnvq] change   get [<i>modifiers</i>] <i>destination</i> [<i>gateway</i> [<i>args</i>]] <b>route</b> [-n] monitor [<i>modifiers</i>] <b>route</b> [-n] flush [<i>modifiers</i>] </pre>                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as <code>in.routed(1M)</code> and <code>in.ripngd(1M)</code>.</p> <p>This utility supports a limited number of general options, but a rich command language. It enables the user to specify any arbitrary request that could be delivered by means of the programmatic interface discussed in <code>route(7P)</code>.</p> <p>route uses a routing socket and the new message types <code>RTM_ADD</code>, <code>RTM_DELETE</code>, <code>RTM_GET</code>, and <code>RTM_CHANGE</code>. As such, only the superuser may modify the routing tables.</p>                                                                |
| <b>OPTIONS</b>     | <pre> -f      Flush the routing tables of all gateway entries. If this is used in conjunction        with one of the commands described above, route flushes the gateways        before performing the command.  -n      Prevent attempts to print host and network names symbolically when        reporting actions. This is useful, for example, when all name servers are        down on your local net, and you need a route before you can contact the        name server.  -v      (Verbose) Print additional details.  -q      Suppress all output. </pre>                                                                                                                                                                                    |
| <b>Commands</b>    | <p>route executes one of four <i>commands</i> on a route to a <i>destination</i>. Two additional <i>commands</i> operate globally on all routing information. The six commands are:</p> <pre> add      Add a route. change   Change aspects of a route (such as its gateway). delete   Delete a specific route. flush    Remove all gateway entries from the routing table. get      Lookup and display the route for a destination. monitor  Continuously report any changes to the routing information base,        routing lookup misses, or suspected network partitionings. </pre> <p>The add, delete, and change commands have the following syntax:</p> <pre> route [ -fnvq ] add   delete [ -net   -host ] destination gateway [args] </pre> |

## route(1M)

or

`route [ -fnvq ] change | get [ -net | -host ] destination gateway [args]` where *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed.

### OPERANDS

`route` executes its commands on routes to destinations.

### Destinations

By default, a destination is looked up under the `AF_INET` address family or as an IPv4 address. All symbolic names specified for a destination or gateway are looked up first as a host name, using `getipnodebyname(3SOCKET)`. If this lookup fails in the `AF_INET` case, `getnetbyname(3SOCKET)` is used to interpret the name as that of a network.

An optional modifier may be included on the command line before a *destination*, to force how `route` interprets a destination:

|                     |                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------|
| <code>-host</code>  | Forces the destination to be interpreted as a host.                                                            |
| <code>-net</code>   | Forces the destination to be interpreted as a network.                                                         |
| <code>-inet</code>  | Forces the destination to be interpreted under the <code>AF_INET</code> address family or as an IPv4 address.  |
| <code>-inet6</code> | Forces the destination to be interpreted under the <code>AF_INET6</code> address family or as an IPv6 address. |

In the case of the `AF_INET` address family or an IPv4 address, routes to a particular host may be distinguished from those to a network by interpreting the Internet address specified as the *destination*. If the *destination* has a "local address part" of `INADDR_ANY`, or if the *destination* is the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

For example:

| The following route:         | Is interpreted as:              |
|------------------------------|---------------------------------|
| <code>128.32</code>          | <code>-host 128.0.0.32</code>   |
| <code>128.32.130</code>      | <code>-host 128.32.0.130</code> |
| <code>-net 128.32</code>     | <code>128.32.0.0</code>         |
| <code>-net 128.32.130</code> | <code>128.32.130.0</code>       |

If the destination is directly reachable by way of an interface requiring no intermediary system to act as a gateway, this can be indicated by including one of two optional modifiers after the destination: The `-interface` modifier can be included or a *metric* of 0 can be specified. These modifiers are illustrated in the following alternative examples:

```
example% route add default hostname -interface
example% route add default hostname 0
```

hostname is the name or IP address associated with the network interface all packets should be sent over. On a host with a single network interface, hostname is normally the same as the *nodename* returned by `uname -n` (see `uname(1)`).

In the above examples, the route does not refer to a gateway, but rather to one of the machine's interfaces. Destinations matching such a route are sent out on the interface identified by the *gateway* address. For interfaces using the ARP protocol, this type of route is used to specify *all destinations are local*. That is, a host should ARP for all addresses by adding a default route using one of the two commands listed above.

With the `AF_INET` address family or an IPv4 address, the optional `-netmask` qualifier is intended to manually add subnet routes with netmasks different from that of the implied network interface. The implicit network mask generated in the `AF_INET` case can be overridden by making sure this option, and an ensuing address parameter (to be interpreted as a network mask), follows the destination parameter.

Alternatively, the length of the netmask may be supplied by appending a slash character and the length immediately after the destination. For example:

```
example% route add 192.0.2.32/27 somegatewaywill create an IPv4 route to the
destination 192.0.2.32 with a netmask of 255.255.255.224, and
```

```
example% route add -inet6 3ffe::/16 somegatewaywill create an IPv6 route to the
destination 3ffe:: with a netmask of 16 one-bits followed by 112 zero-bits.
```

## Routing Flags

Routes have associated flags which influence operation of the protocols when sending to destinations matched by the routes. These flags may be set (or sometimes cleared) by including the following corresponding modifiers on the command line:

| Modifier                | Flag                       | Description                             |
|-------------------------|----------------------------|-----------------------------------------|
| <code>-cloning</code>   | <code>RTF_CLONING</code>   | generates a new route on use            |
| <code>-xresolve</code>  | <code>RTF_XRESOLVE</code>  | emit mesg on use (for external lookup)  |
| <code>-iface</code>     | <code>~RTF_GATEWAY</code>  | destination is directly reachable       |
| <code>-static</code>    | <code>RTF_STATIC</code>    | manually added route                    |
| <code>-nostatic</code>  | <code>~RTF_STATIC</code>   | pretend route added by kernel or daemon |
| <code>-reject</code>    | <code>RTF_REJECT</code>    | emit an ICMP unreachable when matched   |
| <code>-blackhole</code> | <code>RTF_BLACKHOLE</code> | silently discard pkts (during updates)  |
| <code>-proto1</code>    | <code>RTF_PROTO1</code>    | set protocol specific routing flag #1   |

## route(1M)

| Modifier | Flag        | Description                           |
|----------|-------------|---------------------------------------|
| -proto2  | RTF_PROTO2  | set protocol specific routing flag #2 |
| -private | RTF_PRIVATE | do not advertise this route           |

The optional modifiers `-rtt`, `-rttvar`, `-sendpipe`, `-recvpipe`, `-mtu`, `-hopcount`, `-expire`, and `-ssthresh` provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These may be individually locked either by preceding each modifier to be locked by the `-lock` meta-modifier, or by specifying that all ensuing metrics may be locked by the `-lockrest` meta-modifier.

The optional modifiers are defined as follows:

|                        |                                                                            |
|------------------------|----------------------------------------------------------------------------|
| <code>-expire</code>   | Lifetime for the entry. This optional modifier is not currently supported. |
| <code>-hopcount</code> | Maximum hop count. This optional modifier is not currently supported.      |
| <code>-mtu</code>      | Maximum MTU in bytes.                                                      |
| <code>-recvpipe</code> | Receive pipe size in bytes.                                                |
| <code>-rtt</code>      | Round trip time in microseconds.                                           |
| <code>-rttvar</code>   | Round trip time variance in microseconds.                                  |
| <code>-sendpipe</code> | Send pipe size in bytes.                                                   |
| <code>-ssthresh</code> | Send pipe size threshold in bytes.                                         |

Some transport layer protocols may support only some of these metrics.

In a change or add command where the destination and gateway are not sufficient to specify the route (for example, , when several interfaces have the same address), the `-ifp` or `-ifa` modifiers may be used to determine the interface or interface address.

**FILES** `/etc/hosts` list of host names and net addresses  
`/etc/networks` list of network names and addresses

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** get(1), uname(1), in.rdisc(1M), netstat(1M), routed(1M), ioctl(2),  
getipnodebyname(3SOCKET), getnetbyname(3SOCKET), hosts(4), networks(4),  
attributes(5), ARP(7P), route(7P), routing(7P)

**DIAGNOSTICS** add [ host | network ] *destination:gateway flags*  
The specified route is being added to the tables. The values printed are from the routing table entry supplied in the `ioctl(2)` call. If the gateway address used was not the primary address of the gateway (the first one returned by `getipnodebyname(3SOCKET)`) the gateway address is printed numerically as well as symbolically.

delete [ host | network ] *destination:gateway flags*  
As above, but when deleting an entry.

*destination done*  
When the `-f` flag is specified, or in the `flush` command, each routing table entry deleted is indicated with a message of this form.

Network is unreachable  
An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.

not in table  
A delete operation was attempted for an entry that is not in the table.

routing table overflow  
An add operation was attempted, but the system was unable to allocate memory to create the new entry.

**NOTES** *All destinations are local* assumes that the routers implement the protocol, `proxy arp`. Normally, using router discovery (see `in.rdisc(1M)`) is more reliable than using `proxy arp`.

Combining the *all destinations are local* route with subnet or network routes can lead to unpredictable results: the search order as it relates to the *all destinations are local* route are undefined and may vary from release to release.

## rpcbind(1M)

| <b>NAME</b>        | rpcbind – universal addresses to RPC program number mapper                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>rpcbind</b> [-d] [-w]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.</p> <p>When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.</p> <p>rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.</p> <p>When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases may be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.</p> <p>rpcbind can only be started by the super-user.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-d Run in debug mode. In this mode, rpcbind will not fork when it starts, will print additional information during operation, and will abort on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.</li><li>-w Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it will write the current list of registered services to /tmp/portmap.file and /tmp/rpcbind.file. Starting rpcbind with the -w option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.</li></ul>                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>FILES</b>       | /tmp/portmap.file<br>/tmp/rpcbind.file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |         |

**NOTES** Terminating `rpcbind` with `SIGKILL` will prevent the warm-start files from being written.

All RPC servers must be restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination; or, the warm-start files are not found by `rpcbind`.

rpc.bootparamd(1M)

**NAME** rpc.bootparamd, bootparamd – boot parameter server

**SYNOPSIS** /usr/sbin/rpc.bootparamd [-d]

**DESCRIPTION** rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4)

The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process).

The rpc.bootparamd program can be invoked either by inetd(1M) or directly from the command line.

**OPTIONS** -d Display debugging information.

**FILES** /etc/bootparams boot parameter data base  
/etc/nsswitch.conf configuration file for the name-service switch

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** inetd(1M), bootparams(4), nsswitch.conf(4), attributes(5)

**NOTES** A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b> | <p>rpcinfo makes an RPC call to an RPC server and reports what it finds.</p> <p>In the first synopsis, <i>rpcinfo</i> lists all the registered RPC services with <i>rpcbind</i> on <i>host</i>. If <i>host</i> is not specified, the local host is the default. If <i>-s</i> is used, the information is displayed in a concise format.</p> <p>In the second synopsis, <i>rpcinfo</i> lists all the RPC services registered with <i>rpcbind</i>, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the <i>rpcbind</i> protocol).</p> <p>The third synopsis makes an RPC call to procedure 0 of <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> and reports whether a response was received. <i>transport</i> is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote <i>rpcbind</i>.</p> <p>The <i>prognum</i> argument is a number that represents an RPC program number (see <i>rpc(4)</i>).</p> <p>If a <i>versnum</i> is specified, <i>rpcinfo</i> attempts to call that version of the specified <i>prognum</i>. Otherwise, <i>rpcinfo</i> attempts to find all the registered version numbers for the specified <i>prognum</i> by calling version 0, which is presumed not to exist; if it does exist, <i>rpcinfo</i> attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for <i>-b</i> and <i>-d</i> options.</p> <p>The <b>EXAMPLES</b> section describe other ways of using <i>rpcinfo</i>.</p> |
| <b>OPTIONS</b>     | <p><i>-T transport</i> Specify the transport on which the service is required. If this option is not specified, <i>rpcinfo</i> uses the transport specified in the <i>NETPATH</i> environment variable, or if that is unset or <i>NULL</i>, the transport in the <i>netconfig(4)</i> database is used. This is a generic</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## rpcinfo(1M)

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | option, and can be used in conjunction with other options as shown in the <i>SYNOPSIS</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -a <i>serv_address</i> | <p>Use <i>serv_address</i> as the (universal) address for the service on <i>transport</i> to ping procedure 0 of the specified <i>prognum</i> and report whether a response was received. The <i>-T</i> option is required with the <i>-a</i> option.</p> <p>If <i>versnum</i> is not specified, <i>rpcinfo</i> tries to ping all available version numbers for that program number. This option avoids calls to remote <i>rpcbind</i> to find the address of the service. The <i>serv_address</i> is specified in universal address format of the given transport.</p> |
| -b                     | <p>Make an RPC broadcast to procedure 0 of the specified <i>prognum</i> and <i>versnum</i> and report all hosts that respond. If <i>transport</i> is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.</p>                                                                                                                                                      |
| -d                     | <p>Delete registration for the RPC service of the specified <i>prognum</i> and <i>versnum</i>. If <i>transport</i> is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser who can delete any service.</p>                                                                                                                                                                                          |
| -l                     | <p>Display a list of entries with a given <i>prognum</i> and <i>versnum</i> on the specified <i>host</i>. Entries are returned for all transports in the same protocol family as that used to contact the remote <i>rpcbind</i>.</p>                                                                                                                                                                                                                                                                                                                                    |
| -m                     | <p>Display a table of statistics of <i>rpcbind</i> operations on the given <i>host</i>. The table shows statistics for each version of <i>rpcbind</i> (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on <i>host</i>.</p>                                                                                                               |
| -n <i>portnum</i>      | <p>Use <i>portnum</i> as the port number for the <i>-t</i> and <i>-u</i> options instead of the port number given by <i>rpcbind</i>. Use of this option avoids a call to the remote <i>rpcbind</i> to find out the address of the service. This option is made obsolete by the <i>-a</i> option.</p>                                                                                                                                                                                                                                                                    |

|    |                                                                                                                                                                                                                                                                                                                                           |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p | Probe <code>rpcbind</code> on <i>host</i> using version 2 of the <code>rpcbind</code> protocol, and display a list of all registered RPC programs. If <i>host</i> is not specified, it defaults to the local host. Note that version 2 of the <code>rpcbind</code> protocol was previously known as the <code>portmapper</code> protocol. |
| -s | Display a concise list of all registered RPC programs on <i>host</i> . If <i>host</i> is not specified, it defaults to the local host.                                                                                                                                                                                                    |
| -t | Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using TCP, and report whether a response was received. This option is made obsolete by the <code>-T</code> option as shown in the third synopsis.                                                                                                          |
| -u | Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using UDP, and report whether a response was received. This option is made obsolete by the <code>-T</code> option as shown in the third synopsis.                                                                                                          |

**EXAMPLES** **EXAMPLE 1** RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with `rpcbind` on the machine named `klaxon` use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the `-s` option to display a more concise list:

```
example% rpcinfo -s klaxon
```

| program | version | netid(s)                        | service | owner     |
|---------|---------|---------------------------------|---------|-----------|
| 100000  | 2,3,4   | tcp,udp,ticlts,ticots,ticotsord | rpcbind | superuser |
| 100008  | 1       | ticotsord,ticots,ticlts,udp,tcp | walld   | superuser |
| 100002  | 2,1     | ticotsord,ticots,ticlts,udp,tcp | rusersd | superuser |
| 100001  | 2,3,4   | ticotsord,ticots,tcp,ticlts,udp | rstatd  | superuser |
| 100012  | 1       | ticotsord,ticots,ticlts,udp,tcp | sprayd  | superuser |
| 100007  | 3       | ticotsord,ticots,ticlts,udp,tcp | ypbind  | superuser |
| 100029  | 1       | ticotsord,ticots,ticlts         | keyserv | superuser |
| 100078  | 4       | ticotsord,ticots,ticlts         | kerbd   | superuser |
| 100024  | 1       | ticotsord,ticots,ticlts,udp,tcp | status  | superuser |

## rpcinfo(1M)

**EXAMPLE 1** RPC services. (Continued)

---

|        |     |                                 |          |           |
|--------|-----|---------------------------------|----------|-----------|
| 100021 | 2,1 | ticotsord,ticots,ticlts,udp,tcp | nlockmgr | superuser |
| 100020 | 1   | ticotsord,ticots,ticlts,udp,tcp | llockmgr | superuser |

---

To show whether the RPC service with program number *prognum* and version *versnum* is registered on the machine named *klaxon* for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```

To show all RPC services registered with version 2 of the *rpcbind* protocol on the local machine use:

```
example% rpcinfo -p
```

To delete the registration for version 1 of the *walld* (program number 100008) service for all transports use:

```
example# rpcinfo -d 100008 1
```

or

```
example# rpcinfo -d walld 1
```

| <b>NAME</b>        | rpc.nisd, nisd – NIS+ service daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/rpc.nisd [-ACDFhlv] [-Y [-B [-t <i>netid</i>]]] [-d <i>dictionary</i>]<br/>[-L <i>load</i>] [-S <i>level</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>rpc.nisd</code> daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines which serve a portion of the NIS+ namespace.</p> <p><code>rpc.nisd</code> is usually started from a system startup script.</p> <p>The <code>-B</code> option causes <code>rpc.nisd</code> to start an auxiliary process, <code>rpc.nisd_resolv</code>, which provides ypserv compatible DNS forwarding for NIS host requests. <code>rpc.nisd_resolv</code> can also be started independently. See <code>rpc.nisd_resolv(1M)</code> for more information on using <code>rpc.nisd_resolv</code> independently.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p><code>-A</code> Authentication verbose mode. The daemon logs all the authentication related activities to <code>syslogd(1M)</code> with <code>LOG_INFO</code> priority.</p> <p><code>-C</code> Open diagnostic channel on <code>/dev/console</code>.</p> <p><code>-D</code> Debug mode (don't fork).</p> <p><code>-F</code> Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.</p> <p><code>-h</code> Print list of options.</p> <p><code>-v</code> Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon (see <code>syslogd(1M)</code>) at <code>LOG_INFO</code> priority. This option is most useful for debugging problems with the service (see also <code>-A</code> option).</p> <p><code>-Y</code> Put the server into NIS (YP) compatibility mode. When operating in this mode, the NIS+ server will respond to NIS Version 2 requests using the version 2 protocol. Because the YP protocol is not authenticated, only those items that have read access to nobody (the unauthenticated request) will be visible through the V2 protocol. It supports only the standard Version 2 maps in this mode (see <code>-B</code> option and <code>NOTES</code> in <code>ypfiles(4)</code>).</p> <p><code>-B</code> Provide ypserv compatible DNS forwarding for NIS host requests. The DNS resolving process, <code>rpc.nisd_resolv</code>, is started and controlled by <code>rpc.nisd</code>. This option requires that the <code>/etc/resolv.conf</code> file be setup for communication with a DNS nameserver. The <code>nslookup</code> utility can be used to verify communication with a DNS nameserver. See <code>resolv.conf(4)</code> and <code>nslookup(1M)</code>.</p> |

## rpc.nisd(1M)

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>-t netid</i>      | Use <i>netid</i> as the transport for communication between <code>rpc.nisd</code> and <code>rpc.nisd_resolv</code> . The default transport is <code>ticots(7D)</code> ( <code>tcp</code> on SunOS 4.x systems).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>-d dictionary</i> | Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the <code>db_initialize</code> function.>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>-L number</i>     | Specify the “load” the NIS+ service is allowed to place on the server. The load is specified in terms of the <i>number</i> of child processes that the server may spawn. This <i>number must</i> be at least 1 for the callback functions to work correctly. The default is 128.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>-S level</i>      | Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2.<br><br>0        Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.<br><br>1        At security level 1, the daemon accepts both <code>AUTH_SYS</code> and <code>AUTH_DES</code> credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since <code>AUTH_SYS</code> credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.<br><br>2        At security level 2, the daemon only accepts authentication using the security mechanisms configured by <code>nisauthconf(1M)</code> . The default security mechanism is <code>AUTH_DES</code> . Security level 2 is the default if the <code>-S</code> option is not used. |

### EXAMPLES    **EXAMPLE 1** Setting up the NIS+ service.

The following example sets up the NIS+ service.

```
example% rpc.nisd
```

### **EXAMPLE 2** Setting Up NIS+ Service Emulating YP With DNS Forwarding

The following example sets up the NIS+ service, emulating YP with DNS forwarding.

```
example% rpc.nisd -YB
```

**EXAMPLE 2** Setting Up NIS+ Service Emulating YP With DNS Forwarding (Continued)

**ENVIRONMENT  
VARIABLES**

**NETPATH** The transports that the NIS+ service will use can be limited by setting this environment variable (see `netconfig(4)`).

**FILES**

`/var/nis/data/parent.object` This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.

`/var/nis/data/root.object` This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify(3NSL)` interface.

`/etc/init.d/rpc` Initialization script for NIS+.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

rpc.nisd\_resolv(1M)

**NAME** | rpc.nisd\_resolv, nisd\_resolv – NIS+ service daemon

**SYNOPSIS** | **rpc.nisd\_resolv** [-v | -V] [-F [-C *fd*]] [-t *xx*] [-p *yy*]

**DESCRIPTION** | **rpc.nisd\_resolv** is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both **ypserv** and **rpc.nisd** that are running in the NIS compatibility mode. It is generally started by invoking **rpc.nisd(1M)** with the **-B** option or **ypserv(1M)** with the **-d** option. Although it is not recommended, **rpc.nisd\_resolv** can also be started independently with the following options.

**OPTIONS** |

- F        Run in foreground.
- C *fd*    Use *fd* for service xprt (from **nisd**).
- v        Verbose. Send output to the syslog daemon.
- V        Verbose. Send output to stdout.
- t *xx*    Use transport *xx*.
- p *yy*    Use transient program# *yy*.

**ATTRIBUTES** | See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** | **nslookup(1M)**, **rpc.nisd(1M)**, **resolv.conf(4)**, **attributes(5)**

**NOTES** | This command requires that the **/etc/resolv.conf** file be setup for communication with a DNS nameserver. The **nslookup** utility can be used to verify communication with a DNS nameserver. See **resolv.conf(4)** and **nslookup(1M)**.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | rpc.nispasswd, nispasswd – NIS+ password update daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <b>/usr/sbin/rpc.nispasswd</b> [-a <i>attempts</i> ] [-c <i>minutes</i> ] [-D] [-g] [-v]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>rpc.nispasswd daemon is an ONC+ RPC service that services password update requests from nispasswd(1) and yppasswd(1). It updates password entries in the NIS+ passwd table.</p> <p>rpc.nispasswd is normally started from a system startup script after the NIS+ server ( rpc.nisd(1M)) has been started. rpc.nispasswd will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if rpc.nisd(1M) is running in NIS(YF) compatibility mode (the -Yoption) and will register as yppasswd for NIS(YF) clients as well.</p> <p>rpc.nispasswd will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords.</p> <p>rpc.nispasswd has to be run by a superuser.</p>                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>-a <i>attempts</i>      Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are syslogd(1M) and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to 3.</p> <p>-c <i>minutes</i>      Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to 30minutes.</p> <p>-D                  Debug. Run in debugging mode.</p> <p>-g                  Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ cred table.</p> <p>-v                  Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.</p> |
| <b>EXIT STATUS</b> | <p>0                  success</p> <p>1                  an error has occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>FILES</b>       | /etc/init.d/rpc                  initialization script for NIS+                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/rpc.rexd [-s]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                 |              |                                 |          |         |          |                                 |
| <b>DESCRIPTION</b> | <p>rpc.rexd is the Sun RPC server for remote program execution. This daemon is started by inetd(1M) whenever a remote execution request is made.</p> <p>For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by rlogin(1). This daemon may use NFS to mount file systems specified in the remote execution request.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |                                 |              |                                 |          |         |          |                                 |
| <b>SECURITY</b>    | <p>rpc.rexd uses pam(3PAM) for account and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for rpc.rexd. Here is a partial pam.conf file with rpc.rexd entries for account and session management using the UNIX module.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="padding: 2px;">rpc.rexd</td> <td style="padding: 2px;">account</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;">/usr/lib/security/pam_unix.so.1</td> </tr> <tr> <td style="padding: 2px;">rpc.rexd</td> <td style="padding: 2px;">session</td> <td style="padding: 2px;">required</td> <td style="padding: 2px;">/usr/lib/security/pam_unix.so.1</td> </tr> </table> <p>If there are no entries for the rpc.rexd service, then the entries for the "other" service will be used. rpc.rexd uses the <code>getpwnid()</code> call to determine whether the given user is a legal user.</p> | rpc.rexd       | account                         | required     | /usr/lib/security/pam_unix.so.1 | rpc.rexd | session | required | /usr/lib/security/pam_unix.so.1 |

| Availability       | SUNWnisu                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                 |              |                                 |          |         |          |                                 |

rpc.rexd(1M)

**SEE ALSO** chkey(1), on(1), rlogin(1), inetd(1M), pam(3PAM), inetd.conf(4), pam.conf(4),  
publickey(4), attributes(5), pam\_unix(5)

**DIAGNOSTICS** Diagnostic messages are normally printed on the console, and returned to the  
requestor.

**NOTES** Root cannot execute commands using rexd client programs such as on(1).

**NAME** | rpc.rstatd, rstatd – kernel statistics server

**SYNOPSIS** | `/usr/lib/netsvc/rstat/rpc.rstatd`

**DESCRIPTION** | `rpc.rstatd` is a server which returns performance statistics obtained from the kernel. `rup(1)` uses `rpc.rstatd` to collect the uptime information that it displays.

`rpc.rstatd` is an RPC service.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `rup(1)`, `inetd(1M)`, `services(4)`, `attributes(5)`

rpc.rusersd(1M)

**NAME** rpc.rusersd, rusersd – network username server

**SYNOPSIS** /usr/lib/netsvc/rusers/rpc.rusersd

**DESCRIPTION** rpc.rusersd is a server that returns a list of users on the host. The rpc.rusersd daemon may be started by inetd(1M) or listen(1M).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** inetd(1M), listen(1M), pmadm(1M), sacadm(1M), attributes(5)

rpc.rwalld(1M)

**NAME** | rpc.rwalld, rwalld – network rwall server

**SYNOPSIS** | `/usr/lib/netsvc/rwall/rpc.rwalld`

**DESCRIPTION** | `rpc.rwalld` is a server that handles `rwall(1M)` requests. It is implemented by calling `wall(1M)` on all the appropriate network machines. The `rpc.rwalld` daemon may be started by `inetd(1M)` or `listen(1M)`.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `inetd(1M)`, `listen(1M)`, `rwall(1M)`, `wall(1M)`, `attributes(5)`

rpc.sprayd(1M)

**NAME** | rpc.sprayd, sprayd – spray server

**SYNOPSIS** | `/usr/lib/netsvc/spray/rpc.sprayd`

**DESCRIPTION** | `rpc.sprayd` is a server that records the packets sent by `spray(1M)`. The `rpc.sprayd` daemon may be started by `inetd(1M)` or `listen(1M)`.

The service provided by `rpc.sprayd` is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `inetd(1M)` `listen(1M)`, `pmadm(1M)`, `sacadm(1M)`, `spray(1M)`, `attributes(5)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>DESCRIPTION</b> | <p>rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are only changed if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory.</p> <p>If the -D option is given, the passwd, shadow, or passwd.adjunct files are located under the directory path specified with -D.</p> <p>If the -noshell, -nogecos or -nopw options are given, these fields may not be changed remotely using chfn, chsh, or passwd(1).</p> <p>If the -m option is given, a make(1) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. Any arguments following the flag are passed to make.</p> <p>The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally.</p> <p>The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time.</p> <p>The daemon is started automatically on the master server of the passwd map by the /etc/init.d/rpc script (see makedbm(1M))</p> <p>The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of "-D /var/yp" the server checks for a "/var/yp/security/passwd.adjunct" file.</p> <p>If there is only a passwd file, then the encrypted password is expected in the second field. If there is a passwd and a passwd.adjunct file, the encrypted password is</p> |

## rpc.yppasswdd(1M)

expected in the second field of the adjunct file with `##username` in the second field of the `passwd` file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**NOTES** If `make` has not been installed and the `-m` option is given, the daemon outputs a warning and proceeds, effectively ignoring the `-m` flag.

When using the `-D` option, you should make sure that the `PWDIR` of the `/var/yp/Makefile` is set accordingly.

The second listed syntax is supplied only for backwards compatibility and may be removed in a future release of this daemon.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

- NAME** rpc.yppupdated, yppupdated – server for changing NIS information
- SYNOPSIS** `/usr/lib/netsvc/yp/rpc.yppupdated [-is]`
- DESCRIPTION** yppupdated is a daemon that updates information in the Network Information Service (NIS). yppupdated consults the `updaters(4)` file in the `/var/yp` directory to determine which NIS maps should be updated and how to change them.
- By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).
- OPTIONS**
- i Accept RPC calls with the insecure AUTH\_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.
  - s Accept only calls authenticated using the secure RPC mechanism (AUTH\_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.
- FILES** `/var/yp/updaters` Configuration file for `rpc.updated` command.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>NAME</b>        | rpld – IA Network Booting RPL (Remote Program Load) Server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/rpld [-fdDMb1gz] <i>interface</i><br/>/usr/sbin/rpld -a [-fdDMb1gz]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The RPL server provides network booting functionality to IA clients by listening to boot requests from them according to the RPL protocol specifications. Boot requests can be generated by clients using the boot floppy supplied in the IA distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process.</p> <p>In the first synopsis, the interface parameter names the network interface upon which rpld is to listen for requests. For example:</p> <pre>/usr/sbin/rpld /dev/le0<br/>/usr/sbin/rpld /dev/smc0</pre> <p>In the second synopsis, rpld locates all of the network interfaces present on the system and starts a daemon process for each one.</p> <p>The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests.</p> <p>Network boot IA clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the <code>ethers(4)</code> and the <code>bootparams(4)</code> databases. The <code>ethers</code> database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The <code>bootparams</code> database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section <code>Client Configuration</code> for information on how to set up these databases.</p> <p>To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some run-time parameters and print out useful status information. See the sub-section <code>Signals</code> for details.</p> <p>The RPL server is not limited to the ability to boot only IA clients. If properly configured, the server should be able to download any bootfiles to the clients.</p> |

**Client  
Configuration**

The following configuration information is specific to booting IA clients.

In order to allow clients to boot IA from across the network, the client's information has to be pre-configured in two databases: `ethers(4)` and `bootparams(4)`. Both databases can be accessed through NIS. Refer to *Solaris 8 Advanced Installation Guide* for information on how to configure a diskless IA client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The `ethers` database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the `ethers` database.

The bulk of the configuration is done in the `bootparams` database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the `bootparams` RPC in `bootparamd(1M)`. Three more keywords have been defined for the RPL server. They are `numbootfiles`, `bootfile`, and `bootaddr`. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

`numbootfiles` Specifies the number of files to be downloaded to the network boot client. The format of this option is:

```
numbootfiles=n
```

Always use `numbootfiles=3` to boot IA across the network.

`bootfile` Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 129.181.32.15:

```
bootfile=/rplboot/129.181.32.15.hw.com:45000
bootfile=/rplboot/129.181.32.15.glue.com:35000
bootfile=/rplboot/129.181.32.15.inetboot=8000
```

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this `hw.com` bootfile is also a suggested value and if possible should not be changed. The address of 35000 for `glue.com` is a suggested value that, if possible, should not be changed. The address of 8000 for `inetboot` is an absolute requirement and should never be changed.

## rpld(1M)

These files, when created following the procedures in the *Solaris 8 Advanced Installation Guide* are actually symbolic links to the real file to be downloaded to the client. `hw.com` is linked to a special driver that corresponds to the network interface card of the client. `glue.com` and `inetboot` are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

`bootaddr`      The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where `glue.com` is being loaded. If possible, always use:

```
bootaddr=35000
```

### OPTIONS

- `-f` config filename.      Use this to specify a configuration file name other than the system default `/etc/rpld.conf` file.
- `-d` debug level.      Specify a level of 0 if you do not want any error or warning messages to be generated, or a level from 1 to 9 for increasing amounts of messages. This option corresponds to the *DebugLevel* setting in the configuration file. The default value is 0. Note that it is best to limit the level to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.
- `-D` debug destination.      Specify 0 to send error or warning messages to standard output, 1 to `syslogd`, and 2 to the log file. This option corresponds to the *DebugDest* setting in the configuration file. The default value is 2.
- `-M` maximum clients.      Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the *MaxClients* setting in the configuration file. A value of `-1` means unlimited, and the actual number will depend on available system resources. The default value is `-1`.
- `-b` background mode.      Specify 1 to run the server in the background and relinquish the controlling terminal, or 0 to run in the foreground without relinquishing the controlling terminal. This option corresponds to the *BackGround* setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the `-D` option above, the server cannot be run in background

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| -l log filename.      | <p>Specify an alternate log file name to hold the error or warning messages in connection with the -D 2 option or the configuration file <i>DebugDest = 2</i> setting. This option corresponds to the <i>LogFile</i> setting in the configuration file. The default is <code>/var/spool/rpld.log</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -s start delay count. | <p>This option corresponds to the <i>StartDelay</i> setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type 1 protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to 1. The delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is 20.</p> |
| -g delay granularity. | <p>This corresponds to the <i>DelayGran</i> setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that works best with the speed of the client and no retransmission request will be needed. The default value is 2.</p>                                                                                                                                                                                                                                                                                                             |
| -z frame size.        | <p>This option corresponds to the <i>FrameSize</i> setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## rpld(1M)

ethernet/802.3, the maximum physical frame size is 1500 octets. The default value is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

**Signals** The RPL server accepts two signals to change run-time parameters and display status information, respectively:

**HANGUP** This will cause the RPL server to reread the default configuration file `/etc/rpld.conf` or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such as *DebugLevel*, *DebugDest*, *LogFile*, *DelayGran*, and *FrameSize*. For *MaxClients*, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the *MaxClients* parameter. For *StartDelay*, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the *BackGround* parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.

**USR1** This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by *DebugDest*.

**FILES** `/usr/sbin/rpld`  
`/etc/rpld.conf`  
`/var/spool/rpld.log`  
`/etc/ethers`  
`/etc/bootparams`  
`/rplboot`

- NAME** rquotad – remote quota server
- SYNOPSIS** `/usr/lib/nfs/rquotad`
- DESCRIPTION** rquotad is an rpc(4) server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by quota(1M) to display user quotas for remote file systems. The rquotad daemon is normally invoked by inetd(1M).
- FILES** quotas quota file at the file system root
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>        | rsh, restricted_shell – restricted shell command interpreter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/lib/rsh [-acefhiknprstuvx] [argument...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>rsh is a limiting version of the standard command interpreter <code>sh</code>, used to restrict logins to execution environments whose capabilities are more controlled than those of <code>sh</code> (see <code>sh(1)</code> for complete description and usage).</p> <p>When the shell is invoked, it scans the environment for the value of the environmental variable, <code>SHELL</code>. If it is found and <code>rsh</code> is the file name part of its value, the shell becomes a restricted shell.</p> <p>The actions of <code>rsh</code> are identical to those of <code>sh</code>, except that the following are disallowed:</p> <ul style="list-style-type: none"><li>■ changing directory (see <code>cd(1)</code>),</li><li>■ setting the value of <code>\$PATH</code>,</li><li>■ specifying path or command names containing <code>/</code>,</li><li>■ redirecting output (<code>&gt;</code> and <code>&gt;&gt;</code>).</li></ul> <p>The restrictions above are enforced after <code>.profile</code> is interpreted.</p> <p>A restricted shell can be invoked in one of the following ways:</p> <ol style="list-style-type: none"><li>1. <code>rsh</code> is the file name part of the last entry in the <code>/etc/passwd</code> file (see <code>passwd(4)</code>);</li><li>2. the environment variable <code>SHELL</code> exists and <code>rsh</code> is the file name part of its value; the environment variable <code>SHELL</code> needs to be set in the <code>.login</code> file;</li><li>3. the shell is invoked and <code>rsh</code> is the file name part of argument 0;</li><li>4. the shell is invoked with the <code>-r</code> option.</li></ol> <p>When a command to be executed is found to be a shell procedure, <code>rsh</code> invokes <code>sh</code> to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.</p> <p>The net effect of these rules is that the writer of the <code>.profile</code> (see <code>profile(4)</code>) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably <i>not</i> the login directory).</p> <p>The system administrator often sets up a directory of commands (that is, <code>/usr/rbin</code>) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, <code>red</code>.</p> |
| <b>EXIT STATUS</b> | Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**NOTES** The restricted shell, `/usr/lib/rsh`, should not be confused with the remote shell, `/usr/bin/rsh`, which is documented in `rsh(1)`.

rtc(1M)

**NAME** | `rtc` – provide all real-time clock and GMT-lag management

**SYNOPSIS** | `/usr/sbin/rtc [-c] [-z zone-name]`

**DESCRIPTION** | The `rtc` command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Greenwich Mean Time (GMT), while MS-DOS systems utilize local time.

Without arguments, `rtc` displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by `rtc-z zone-name`.

The `rtc` command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as `date(1)` and `rdate(1M)`, which are used to set the time on a system, invoke `/usr/sbin/rtc -c` to ensure that daylight savings time (DST) is corrected for properly.

**OPTIONS** | `-c` | This option checks for DST and makes corrections if necessary. It is normally run once a day by a cron job.

If there is no RTC time zone or `/etc/rtc_config` file, this option will do nothing.

`-z zone-name` | This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file `/etc/rtc_config` with the name of the specified zone and the current GMT lag for that zone. If there is an existing `rtc_config` file, this command will update it. If not, this command will create it.

**FILES** | `/etc/rtc_config` | The data file used to record the time zone and GMT lag. This file is completely managed by `/usr/sbin/rtc`, and it is read by the kernel.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees.</p> <p>runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.</p> <p>runacct breaks its processing into separate, restartable <i>states</i> using statefile to remember the last <i>state</i> completed. It accomplishes this by writing the <i>state</i> name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. <i>states</i> are executed in the following order:</p> <table border="0"> <tr> <td style="padding-right: 20px;">SETUP</td> <td>Move active accounting files into working files.</td> </tr> <tr> <td>WTMPFIX</td> <td>Verify integrity of wtmpx file, correcting date changes if necessary.</td> </tr> <tr> <td>CONNECT</td> <td>Produce connect session records in tacct .h format.</td> </tr> <tr> <td>PROCESS</td> <td>Convert process accounting records into tacct .h format.</td> </tr> <tr> <td>MERGE</td> <td>Merge the connect and process accounting records.</td> </tr> <tr> <td>FEEES</td> <td>Convert output of chargefee into tacct .h format, merge with connect, and process accounting records.</td> </tr> <tr> <td>DISK</td> <td>Merge disk accounting records with connect, process, and fee accounting records.</td> </tr> <tr> <td>MERGETACCT</td> <td>Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.</td> </tr> <tr> <td>CMS</td> <td>Produce command summaries.</td> </tr> <tr> <td>USEREXIT</td> <td>Any installation dependent accounting programs can be included here.</td> </tr> <tr> <td>CLEANUP</td> <td>Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mddd</i> is necessary if runacct is being restarted. <i>mddd</i> specifies the month and day for which runacct</td> </tr> </table> | SETUP | Move active accounting files into working files. | WTMPFIX | Verify integrity of wtmpx file, correcting date changes if necessary. | CONNECT | Produce connect session records in tacct .h format. | PROCESS | Convert process accounting records into tacct .h format. | MERGE | Merge the connect and process accounting records. | FEEES | Convert output of chargefee into tacct .h format, merge with connect, and process accounting records. | DISK | Merge disk accounting records with connect, process, and fee accounting records. | MERGETACCT | Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct. | CMS | Produce command summaries. | USEREXIT | Any installation dependent accounting programs can be included here. | CLEANUP | Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mddd</i> is necessary if runacct is being restarted. <i>mddd</i> specifies the month and day for which runacct |
| SETUP              | Move active accounting files into working files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |                                                  |         |                                                                       |         |                                                     |         |                                                          |       |                                                   |       |                                                                                                       |      |                                                                                  |            |                                                                                                                            |     |                            |          |                                                                      |         |                                                                                                                                                                                                                                                                                                                                                                                                    |

| CLEANUP            | Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mddd</i> is necessary if runacct is being restarted. <i>mddd</i> specifies the month and day for which runacct                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |       |                                                  |         |                                                                       |         |                                                     |         |                                                          |       |                                                   |       |                                                                                                       |      |                                                                                  |            |                                                                                                                            |     |                            |          |                                                                      |         |                                                                                                                                                                                                                                                                                                                                                                                                    |

## runacct(1M)

will rerun the accounting. The entry point for processing is based on the contents of *statefile*; to override this, include the desired *state* on the command line to designate where processing should begin.

**EXAMPLES** **EXAMPLE 1** A sample display of using *runacct* command.

The following example starts *runacct*:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

The following example restarts *runacct*:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

The following example restarts *runacct* at a specific *state*:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

**FILES**

- /var/adm/wtmpx*  
history of user access and administration information
- /var/adm/pacctincr*
- /var/adm/acct/nite/active*
- /var/adm/acct/nite/daytacct*
- /var/adm/acct/nite/lock*
- /var/adm/acct/nite/lock1*
- /var/adm/acct/nite/lastdate*
- /var/adm/acct/nite/statefile*

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWaccu        |

**SEE ALSO** *acctcom(1)*, *mail(1)*, *acct(1M)*, *acctcms(1M)*, *acctcon(1M)*, *acctmerg(1M)*, *acctprc(1M)*, *acctsh(1M)*, *cron(1M)*, *fwtmp(1M)*, *acct(2)*, *acct(3HEAD)*, *utmpx(4)*, *attributes(5)*

**NOTES** It is not recommended to restart *runacct* in the *SETUP state*. Run *SETUP* manually and restart using:

```
runacct mmd WTMPFIX
```

If `runacct` failed in the *PROCESS state*, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

```
6000 distinct sessions
1000 distinct terminal lines
2000 distinct login names
```

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts attempt to execute `turnacct switch` simultaneously.

rwall(1M)

**NAME** | rwall – write to all users over a network

**SYNOPSIS** | `/usr/sbin/rwall hostname...`  
| `/usr/sbin/rwall -n netgroup...`  
| `/usr/sbin/rwall -h hostname -n netgroup`

**DESCRIPTION** | rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:  
| Broadcast Message . . .  
|  
| to all users logged in on the specified host machines. With the -n option, it sends to the specified network groups.

**OPTIONS** | -n *netgroup*      Send the broadcast message to the specified network groups.  
| -h *hostname*      Specify the hostname, the name of the host machine.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | `inetd(1M)`, `listen(1M)`, `pmadm(1M)`, `sacadm(1M)`, `wall(1M)`, `attributes(5)`

**NOTES** | The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |

| <b>DESCRIPTION</b>                             | The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |
| <b>Customizing the SAC Environment</b>         | When <i>sac</i> is invoked, it first looks for the per-system configuration script <i>/etc/saf/_sysconfig</i> . <i>sac</i> interprets <i>_sysconfig</i> to customize its own environment. The modifications made to the SAC environment by <i>_sysconfig</i> are inherited by all the children of the SAC. This inherited environment may be modified by the children.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |
| <b>Starting Port Monitors</b>                  | After it has interpreted the <i>_sysconfig</i> file, the <i>sac</i> reads its administrative file <i>/etc/saf/_sactab</i> . <i>_sactab</i> specifies which port monitors are to be started. For each port monitor to be started, <i>sac</i> forks a child (see <i>fork(2)</i> ) and creates a <i>utmpx</i> entry with the <i>type</i> field set to <i>LOGIN_PROCESS</i> . Each child then interprets its per-port monitor configuration script <i>/etc/saf/pmtag/_config</i> , if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process <i>execs</i> the port monitor, using the command found in the <i>_sactab</i> entry. (See <i>sacadm</i> ; this is the command given with the <i>-c</i> option when the port monitor is added to the system.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |
| <b>Polling Port Monitors to Detect Failure</b> | The <i>-t</i> option sets the frequency with which <i>sac</i> polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |
| <b>Administrative functions</b>                | The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below.<br><br>When queried ( <i>sacadm</i> with either <i>-l</i> or <i>-L</i> ), the Service Access Controller returns the status of the port monitors specified, which <i>sacadm</i> prints on the standard output. A port monitor may be in one of six states:<br><br><table border="0" style="width: 100%;"> <tr> <td style="width: 20%;">ENABLED</td> <td>The port monitor is currently running and is accepting connections. See <i>sacadm(1M)</i> with the <i>-e</i> option.</td> </tr> <tr> <td>DISABLED</td> <td>The port monitor is currently running and is not accepting connections. See <i>sacadm</i> with the <i>-d</i> option, and see <i>NOTRUNNING</i>, below.</td> </tr> <tr> <td>STARTING</td> <td>The port monitor is in the process of starting up. <i>STARTING</i> is an intermediate state on the way to <i>ENABLED</i> or <i>DISABLED</i>.</td> </tr> <tr> <td>FAILED</td> <td>The port monitor was unable to start and remain running.</td> </tr> <tr> <td>STOPPING</td> <td>The port monitor has been manually terminated but has not completed its shutdown procedure. <i>STOPPING</i> is an intermediate state on the way to <i>NOTRUNNING</i>.</td> </tr> </table> | ENABLED | The port monitor is currently running and is accepting connections. See <i>sacadm(1M)</i> with the <i>-e</i> option. | DISABLED | The port monitor is currently running and is not accepting connections. See <i>sacadm</i> with the <i>-d</i> option, and see <i>NOTRUNNING</i> , below. | STARTING | The port monitor is in the process of starting up. <i>STARTING</i> is an intermediate state on the way to <i>ENABLED</i> or <i>DISABLED</i> . | FAILED | The port monitor was unable to start and remain running. | STOPPING | The port monitor has been manually terminated but has not completed its shutdown procedure. <i>STOPPING</i> is an intermediate state on the way to <i>NOTRUNNING</i> . |
| ENABLED                                        | The port monitor is currently running and is accepting connections. See <i>sacadm(1M)</i> with the <i>-e</i> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |         |                                                                                                                      |          |                                                                                                                                                         |          |                                                                                                                                               |        |                                                          |          |                                                                                                                                                                        |
| DISABLED                                       | The port monitor is currently running and is not accepting connections. ## sac(1M)

**NOTRUNNING** The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal “not running” state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the `DISABLED` state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a `DISABLED` state as well as the `NOTRUNNING` state.

When a port monitor terminates, the SAC removes the `utmpx` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/pmtag/_sactab`.
- The number of times the port monitor has already been restarted.

### SECURITY

`sac` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

```
sac session required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `sac` service, then the entries for the “other” service will be used.

### OPTIONS

`-t sanity_interval` Sets the frequency (*sanity\_interval*) with which `sac` polls the port monitors on the system.

**FILES** /etc/saf/\_sactab  
 /etc/saf/\_sysconfig  
 /var/adm/utmpx  
 /var/saf/\_log

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | sacadm – service access controller administration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre><b>sacadm</b> -a -p <i>pmtag</i> -t <i>type</i> -c <i>cmd</i> -v <i>ver</i> [-f <i>dx</i>] [-n <i>count</i>] [-y <i>comment</i>] [-z <i>script</i>]  <b>sacadm</b> -r -p <i>pmtag</i>  <b>sacadm</b> -s -p <i>pmtag</i>  <b>sacadm</b> -k -p <i>pmtag</i>  <b>sacadm</b> -e -p <i>pmtag</i>  <b>sacadm</b> -d -p <i>pmtag</i>  <b>sacadm</b> -l [-p <i>pmtag</i>   -t <i>type</i>]  <b>sacadm</b> -L [-p <i>pmtag</i>   -t <i>type</i>]  <b>sacadm</b> -g -p <i>pmtag</i> [-z <i>script</i>]  <b>sacadm</b> -G [-z <i>script</i>]  <b>sacadm</b> -x [-p <i>pmtag</i>]</pre>                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions:</p> <ul style="list-style-type: none"><li>■ adds or removes a port monitor</li><li>■ starts or stops a port monitor</li><li>■ enables or disables a port monitor</li><li>■ installs or replaces a per-system configuration script</li><li>■ installs or replaces a per-port monitor configuration script</li><li>■ prints requested port monitor information</li></ul> <p>Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.</p> |
| <b>OPTIONS</b>     | <p>-a Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and /var/saf and adds an entry for the new port monitor to /etc/saf/_sactab. The file _sactab already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the -f option with the -x argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add port monitors.</p>                                                                                                                                     |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c <i>cmd</i>   | Execute the command string <i>cmd</i> to start a port monitor. The -c option may be used only with a -a. A -a option requires a -c.                                                                                                                                                                                                                                                                                                                                                                                        |
| -d              | Disable the port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -e              | Enable the port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -f <i>dx</i>    | The -f option specifies one or both of the following two flags which are then included in the flags field of the <code>_sactab</code> entry for the new port monitor. If the -f option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A -f option with no following argument is illegal.<br><br>d            Do not enable the new port monitor.<br>x            Do not start the new port monitor.                                      |
| -g              | The -g option is used to request output or to install or replace the per-port monitor configuration script <code>/etc/saf/<i>pmtag</i>/_config</code> . -g requires a -p option. The -g option with only a -p option prints the per-port monitor configuration script for port monitor <i>pmtag</i> . The -g option with a -p option and a -z option installs the file <code>script</code> as the per-port monitor configuration script for port monitor <i>pmtag</i> . Other combinations of options with -g are invalid. |
| -G              | The -G option is used to request output or to install or replace the per-system configuration script <code>/etc/saf/_sysconfig</code> . The -G option by itself prints the per-system configuration script. The -G option in combination with a -z option installs the file <code>script</code> as the per-system configuration script. Other combinations of options with a -G option are invalid.                                                                                                                        |
| -k              | Stop port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -l              | The -l option is used to request port monitor information. The -l by itself lists all port monitors on the system. The -l option in combination with the -p option lists only the port monitor specified by <i>pmtag</i> . A -l in combination with the -t option lists all port monitors of type <code>type</code> . Any other combination of options with the -l option is invalid.                                                                                                                                      |
| -L              | The -L option is identical to the -l option except that the output appears in a condensed format.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -n <i>count</i> | Set the restart count to <i>count</i> . If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.                                                                                                                                                                                                                                                                                                                                           |
| -p <i>pmtag</i> | Specifies the tag associated with a port monitor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -r              | Remove port monitor <i>pmtag</i> . <code>sacadm</code> removes the port monitor entry from <code>/etc/saf/_sactab</code> . If the removed port monitor is                                                                                                                                                                                                                                                                                                                                                                  |

## sacadm(1M)

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it SIGTERM to indicate that it should shut down. Note that the port monitor's directory structure remains intact.                                                                                                                                                                                                              |
| -s         | Start a port monitor. The SAC starts the port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                           |
| -t type    | Specifies the port monitor type.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -v ver     | Specifies the version number of the port monitor. This version number may be given as<br><br>-v ' <i>pmspec</i> -V'<br>where <i>pmspec</i> is the special administrative command for port monitor <i>pmtag</i> . This special command is <i>ttynam</i> and <i>nlsadmin</i> for <i>listen</i> . The version stamp of the port monitor is known by the command and is returned when <i>pmspec</i> is invoked with a -V option.                                   |
| -x         | The -x option by itself tells the SAC to read its database file ( <i>_sactab</i> ). The -x option with the -p option tells port monitor <i>pmtag</i> to read its administrative file.                                                                                                                                                                                                                                                                          |
| -y comment | Include <i>comment</i> in the <i>_sactab</i> entry for port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                             |
| -z script  | Used with the -g and -G options to specify the name of a file that contains a configuration script. With the -g option, <i>script</i> is a per-port monitor configuration script; with -G it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-g or -G). Then the copy is edited. Finally, the copy is put in place over the existing script (-g or -G with -z). |

**OUTPUT** If successful, *sacadm* will exit with a status of 0. If *sacadm* fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (-L), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (-l) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is #.

**EXAMPLES** **EXAMPLE 1** A sample output of the *sacadm* command.

The following command line adds a port monitor. The port monitor tag is *npack*; its type is *listen*; if necessary, it will restart three times before failing; its administrative command is *nlsadmin*; and the configuration script to be read is in the file *script*:

```
sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v 'nlsadmin -V' -n 3 -z script
```

Remove a port monitor whose tag is *pmtag*:

```
sacadm -r -p pmtag
```

**EXAMPLE 1** A sample output of the `sacadm` command. (Continued)

Start the port monitor whose tag is `pmtag`:

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

**FILES** `/etc/saf/_sactab`  
`/etc/saf/_sysconfig`  
`/etc/saf/pmtag/_config`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>DESCRIPTION</b> | <p>sadmind is the daemon used by Solstice AdminSuite applications to perform distributed system administration operations.</p> <p>The sadmind daemon is started automatically by the inetd daemon whenever a request to invoke an operation is received. The sadmind daemon process continues to run for 15 minutes after the last request is completed, unless a different idle-time is specified with the -i command line option. The sadmind daemon may be started independently from the command line, for example, at system boot time. In this case, the -i option has no effect; sadmind continues to run, even if there are no active requests.</p> <p>The sadmind daemon process can be configured to write tracing information into a log file by specifying the -c and -l command line options. The -c option specifies a comma-separated list of keywords indicating the types of information to be logged. The following keywords may be useful to you as an administrator:</p> <table><tr><td>System-Info</td><td>Includes messages about when the sadmind daemon was started and stopped.</td></tr><tr><td>Requests</td><td>Includes messages about which operations sadmind invoked and when.</td></tr><tr><td>Errors</td><td>Includes messages about errors that occurred during the daemon execution.</td></tr><tr><td>*</td><td>Includes all possible log messages.</td></tr></table> <p>The -l option enables logging and optionally specifies the path and file name of the log file. If no log file is specified, the default log file /var/adm/admin.log is used.</p> | System-Info        | Includes messages about when the sadmind daemon was started and stopped.                                                          | Requests       | Includes messages about which operations sadmind invoked and when.                                                                                                                                                                                                                                                                                                                                                                                                                                       | Errors | Includes messages about errors that occurred during the daemon execution. | * | Includes all possible log messages. |
| System-Info        | Includes messages about when the sadmind daemon was started and stopped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |
| Requests           | Includes messages about which operations sadmind invoked and when.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |
| Errors             | Includes messages about errors that occurred during the daemon execution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |
| *                  | Includes all possible log messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <table><tr><td>-c <i>keywords</i></td><td>Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.</td></tr><tr><td>-i <i>secs</i></td><td>Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | -c <i>keywords</i> | Specify the types of information to be logged as a comma-separated list of keywords. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance. |        |                                                                           |   |                                     |
| -c <i>keywords</i> | Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |
| -i <i>secs</i>     | Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                           |   |                                     |

- `-l [logfile]` Enable logging and optionally define the path name to the distributed system administration log file. The default log file is:
- ```
/var/adm/admin.log
```
- `-o OW_path_name` Define the path name to the OpenWindows home directory. If this option is not specified, the `sadmin` daemon will use the OpenWindows home directory defined in the `OPENWINHOME` environment variable, if defined; the home directory specified in the `/etc/OPENWINHOME` file, if it exists; or the default directory `/usr/openwin`. When the `sadmin` daemon is started by the `inetd` daemon, the environment variable `OPENWINHOME` is typically not defined. If the OpenWindows home directory is not one of the path names specified (`/usr/openwin` or in the file `/etc/OPENWINHOME`), the `-o` option must be added to the `sadmin` entry in the `inetd.conf(4)` configuration file.
- `-S security_level` Define the level of security to be used by the `sadmin` daemon when checking a client's right to perform an operation on the server system. Security level specifies the authentication mechanism used to provide and check the client's identity. The client's identity must be authenticated by the specified mechanism for `sadmin` to accept his or her request. The system-wide authentication requirements set by the security level may take precedence over any operation-specific requirements. Consequently, the security level can be used system-wide to ensure that all operations meet minimum authentication requirements, regardless of the requirements assigned specifically to an operation. In addition, the security level determines whether `sadmin` will perform authorization access control checking.
- Security level may be one of the following:
- 0 Set authentication type to `NONE`. All clients' user and group identities are set to the `nobody` identity by `sadmin` (see *Solstice AdminSuite 2.1 User's Guide*). If access is granted to `nobody`, `sadmin` executes the operation. Use this level only for testing.

sadmind(1M)

- 1 Set authentication type to `WEAK`. Clients' user and group identities are set by `sadmind` from their authentication credentials. Client identities are accepted by `sadmind` when they have satisfied either `AUTH_SYS` or `AUTH_DES` authentication mechanisms. The authenticated client identity is checked by `sadmind` for authorization to execute the operation. If an operation calls for a stronger security level, `sadmind` demotes the user identity to `nobody`, and then checks whether `nobody` is authorized to execute the operation. Since `AUTH_SYS` client credentials are easily forged, this level should be used only in relatively secure environments. No check is done that the user ID of the client represents the same user on the server system as on the client system. It is assumed that user and group identities are set up consistently on the network. This security level is the default.
- 2 Set authentication type to `STRONG`. Clients' user and group identities are set by `sadmind` from their authentication credential mappings (effectively, user and group IDs from `net.id.byname` for `NIS`, or `cred` table for `NIS+`). Client identities are accepted by `sadmind` only when they have satisfied the `AUTH_DES` authentication mechanism. The `sadmind` daemon checks whether the client identity is authorized to execute the operation. This level provides the most secure environment for executing distributed administration operations. It overrides any weaker level specific to an operation. A `DES` credential must exist for the host running the `sadmind` daemon and all administration client user identities.

-v

Enable the writing of log messages to the system logger, `syslogd`. Messages logged include fatal errors encountered while attempting to start the `sadmind` daemon process and those specified by the `-c` trace message keywords.

EXAMPLES **EXAMPLE 1** Using the `sadmind` command

By default, the line in `/etc/inetd.conf` that starts `sadmind` appears as follows:

```
100232/10      tli      rpc/udp      wait root
/usr/sbin/sadmind sadmind
```

To make a network as secure as possible, change the line to:

```
100232/10      tli      rpc/udp      wait root
/usr/sbin/sadmind sadmind -S 2
```

To minimize delays due to starting up `sadmind`, change the line to include the `-i` option:

```
100232/10      tli      rpc/udp      wait root
/usr/sbin/sadmind sadmind -i 86400
```

In this example, the duration that `sadmind` remains up after the last operation request was completed is extended to 24 hours (86,400 seconds). Extending the timeout period may enhance performance on servers and workstations that frequently run or are administered by applications that use the `sadmind` daemon (for example, Solstice AdminSuite applications such as Host Manager).

FILES `/var/adm/admin.log` distributed system administration default log file
`/etc/inetd.conf` internet servers database file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmfw

SEE ALSO `inetd(1M)`, `rpcbind(1M)`, `inetd.conf(4)`, `attributes(5)`

Solstice AdminSuite 2.1 User's Guide

NOTES Whenever `inetd` fails to start `sadmind`, re-register the RPC number for `sadmind`, 100232, with `rpcbind` by sending the `inetd` process a `SIGHUP` signal:

```
example% kill -HUP pid
or
example% kill -1
```

Sometimes `inetd` does not start `sadmind` in response to system administration requests, even though the `inetd.conf` file has the correct entry for the `sadmind` daemon. This can happen when `sadmind` is started manually from the command line and takes over the previous registration of the `sadmind` RPC number, 100232, by `inetd`. When the manually-started `sadmind` daemon is terminated, the `sadmind`

sadmin(1M)

RPC number, 100232, is de-registered with `rpcbind`. Consequently, system administration requests are ignored by `inetd`.

NAME	saf – Service Access Facility
DESCRIPTION	<p>The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.</p> <p>Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the sac(1M) man page. The administrative levels and associated utilities are documented in the <i>System Administration Guide - Volume II</i>. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.</p>
Port Monitors	<p>A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately.</p> <p>A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.</p> <p>A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.</p> <p>Port Management</p> <p>The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.</p> <p>Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.</p> <p>Activity Monitoring</p> <p>The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.</p>

saf(1M)

Other Port Monitor Functions

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

This section briefly describes other port monitor functions.

Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

Creating utmpx Entries

Port monitors are responsible for creating utmpx entries with the type field set to USER_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmpx entries may in turn be modified by the service. When the service terminates, the utmpx entry must be set to DEAD_PROCESS.

Port Monitor Process IDs and Lock Files

When a port monitor starts, it writes its process id into a file named _pid in the current directory and places an advisory lock on the file.

Changing the Service Environment: Running

doconfig(3NSL) Before invoking the service designated in the port monitor administrative file, _pmtab, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function doconfig(3NSL). Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

Terminating a Port Monitor

A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following:

1. The port monitor enters the stopping state; no further service requests are accepted.
2. Any attempt to re-enable the port monitor will be ignored.
3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping.
4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.

SAF Files This section briefly covers the files used by the SAF.

The Port Monitor Administrative File

A port monitor's current directory contains an administrative file named `_pmtab`; `_pmtab` is maintained by the `pmadm` command in conjunction with a port monitor-specific administrative command.

The port monitor administrative command for a listen port monitor is `nlsadmin(1M)`; the port monitor administrative command for `ttymon` is `ttymadm(1M)`. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.

Per-Service Configuration Files

A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the `_pmtab` file.

Private Port Monitor Files

A port monitor may create private files in the directory `/var/saf/tag`, where `tag` is the name of the port monitor. Examples of private files are log files or temporary files.

The SAC/Port Monitor Interface

The SAC creates two environment variables for each port monitor it starts: `PMTAG` and `ISTATE`.

This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to `sac` messages. `ISTATE` is used to indicate to the port monitor what its initial internal state should be. `ISTATE` is set to "enabled" or "disabled" to indicate that the port monitor is to start in the enabled or disabled state respectively.

The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open `_pmpipe`, in the current directory, to receive messages from the SAC and `./_sacpipe` to send return messages to the SAC.

Message Formats

This section describes the messages that may be sent from the SAC to a port monitor (`sac` messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.

saf(1M)

sac Messages

The format of messages from the SAC is defined by the structure `sacmsg`:

```
struct sacmsg
{
    int sc_size; /* size of optional data portion */
    char sc_type; /* type of message */
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

SC_STATUS	status request
SC_ENABLE	enable message
SC_DISABLE	disable message
SC_READDB	message indicating that the port monitor's <code>_pmtab</code> file should be read

The `sc_size` field indicates the size of the optional data part of the message. See "Message Classes." For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

Port Monitor Messages

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
    char pm_type; /* type of message */
    uchar_t pm_state; /* current state of port monitor */
    char pm_maxclass; /* maximum message class this port
                      monitor understands */
    char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
    int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

PM_STATUS	state information
PM_UNKNOWN	negative acknowledgment

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

PM_STARTING	starting
PM_ENABLED	enabled
PM_DISABLED	disabled

PM_STOPPING stopping

The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. `pm_size` indicates the size of the optional data part of the message. `pm_maxclass` is used to specify a message class. Both are discussed under "Message Classes." In Solaris, always set `pm_maxclass` to 1 and `sc_size` to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.

Message Classes

The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the `pm_maxclass` field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of `pm_maxclass`. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set `pm_maxclass` to 1.

For any given port monitor, messages of class `pm_maxclass` and messages of all classes with values lower than `pm_maxclass` are valid. Thus, if the `pm_maxclass` field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. `pm_size` (an element of the `pmmsg` structure) and `sc_size` (an element of the `sacmsg` structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both `sc_size` and `pm_size` to 0.

Administrative Interface The SAC Administrative File `_sactab`

This section discusses the port monitor administrative files available under the SAC.

The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command `sacadm(1M)` with a `-a` option. `sacadm(1M)` is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.

saf(1M)

PMTAG

A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

PMTYPE

The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. `ttymon` and `listen` are examples of valid port monitor types. The type designator is used to facilitate the administration of groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

FLGS

The flags that are currently defined are:

- d When started, do not enable the port monitor.
- x Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

RCNT

The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

COMMAND

A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

**The Port Monitor
Administrative
File `_pmtab`**

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/pmtag`, where `pmtag` is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, `root`).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port

monitor. The record must also contain port monitor specific data (for example, for a `ttymon` port monitor, this will include the prompt string which is meaningful to `ttymon`). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttynam(1M)` command does this for `ttymon` and `nlsadmin(1M)` does it for `listen`. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

FLGS

Flags with the following meanings may currently be included in this field:

- x Do not enable this port. By default the port is enabled.
- u Create a `utmpx` entry for this service. By default no `utmpx` entry is created for the service.

ID

The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

PMSPECIFIC

Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

COMMENT

A comment associated with the service entry. Port monitors may ignore the `u` flag if creating a `utmpx` entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless `utmpx` entries have been created for them (for example, `login`). Each port monitor administrative file must contain one special comment of the form:

```
# VERSION=value
```

where *value* is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

saf(1M)

**Monitor-Specific
Administrative
Command**

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

**The Port
Monitor/Service
Interface**

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3NSL)`.

Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

**Port Monitor
Requirements**

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in `/etc/utmpx` of type `LOGIN_PROCESS`
- An environment variable, `ISTATE`, is set to "enabled" or "disabled" to indicate the port monitor's correct initial state
- An environment variable, `PMTAG`, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory

- The port monitor is able to create private files in the directory `/var/saf/tag`, where `tag` is the port monitor's tag
- The port monitor is running with user id 0 (root)

Important Files

Relative to its current directory, the following key files exist for a port monitor.

`_config`

The port monitor's configuration script. The port monitor configuration script is run by the SAC. The SAC is started by `init(1M)` as a result of an entry in `/etc/inittab` that calls `sac(1M)`.

`_pid`

The file into which the port monitor writes its process id.

`_pmtab`

The port monitor's administrative file. This file contains information about the ports and services for which the port monitor is responsible.

`_pmpipe`

The FIFO through which the port monitor will receive messages from the SAC.

`svctag`

The per-service configuration script for the service with the tag `svctag`.

`../_sacpipe`

The FIFO through which the port monitor will send messages to `sac(1M)`.

Port Monitor Responsibilities

A port monitor is responsible for performing the following tasks in addition to its port monitor function:

- Write its process id into the file `_pid` and place an advisory lock on the file
- Terminate gracefully on receipt of the signal `SIGTERM`
- Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

- Create a `utmpx` entry if the requested service has the `u` flag set in `_pmtab`
- Port monitors may ignore this flag if creating a `utmpx` entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless `utmpx` entries have been created for them.
- Interpret the per-service configuration script for the requested service, if it exists, by calling the `doconfig(3NSL)` library routine

Configuration Files and Scripts

The library routine `doconfig(3NSL)`, defined in `libnsl.so`, interprets the configuration scripts contained in the files `/etc/saf/_sysconfig` (the per-system configuration file), and `/etc/saf/pmtag/_config` (per-port monitor configuration files); and in `/etc/saf/pmtag/svctag` (per-service configuration files). Its syntax is:

```
#include <sac.h>
int doconfig (int fd, char *script, long rflag);
```

`script` is the name of the configuration script; `fd` is a file descriptor that designates the stream to which stream manipulation operations are to be applied; `rflag` is a bitmask that indicates the mode in which script is to be interpreted. `rflag` may take two values, NORUN and NOASSIGN, which may be or'd. If `rflag` is zero, all commands in the configuration script are eligible to be interpreted. If `rflag` has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If `rflag` has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, `doconfig(3NSL)` is used to interpret a per-service configuration script.

```
    . . .
    if ((i = doconfig (fd, svctag, 0)) != 0){
        error ("doconfig failed on line %d of script %s",i,svctag);
    }
}
```

The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3NSL)` manpage. When the SAC is started, it calls the `doconfig(3NSL)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user. Using the language described in the `doconfig(3NSL)` manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

The Configuration Language

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

`assign` *variable=value*

Used to define environment variables; *variable* is the name of the environment variable and *value* is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. *value* may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push` *module1[, module2, module3, . . .]*

Used to push STREAMS modules onto the stream designated by `fd`; *module1* is the name of the first module to be pushed, *module2* is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop` [*module*]

Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If *module* is the special keyword `ALL`, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

`runwait` *command*

The `runwait` command runs a command and waits for it to complete; *command* is the path name of the command to be run. The command is run with `/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if *command* cannot be found or cannot be executed, or if *command* exits with a nonzero status.

`run` *command*

The `run` command is identical to `runwait` except that it does not wait for *command* to complete; *command* is the path name of the command to be run. `run` will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The `doconfig` interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the `sh(1)` man page. The initial set of built-in commands is: `cd`, `ulimit`, `umask`.

saf(1M)

Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>
# include <fcntl.h>
# include <signal.h>
# include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
int argc;
char *argv[];
{
    char *istate;
    strcpy(Tag, getenv("PMTAG"));
/*
 * open up a log file in port monitor's private directory
 */
    sprintf(Scratch, "/var/saf/%s/log", Tag);
    Fp = fopen(Scratch, "a+");
    if (Fp == (FILE *)NULL)
        exit(1);
    log(Fp, "starting");
/*
 * retrieve initial state (either "enabled" or "disabled") and set
 * State accordingly
 */
    istate = getenv("ISTATE");
    sprintf(Scratch, "ISTATE is %s", istate);
    log(Fp, Scratch);
    if (!strcmp(istate, "enabled"))
        State = PM_ENABLED;
    else if (!strcmp(istate, "disabled"))
        State = PM_DISABLED;
    else {
        log(Fp, "invalid initial state");
        exit(1);
    }
    sprintf(Scratch, "PMTAG is %s", Tag);
    log(Fp, Scratch);
/*
 * set up pid file and lock it to indicate that we are active
 */
    Tfp = fopen("_pid", "w");
    if (Tfp == (FILE *)NULL) {
        log(Fp, "couldn't open pid file");
        exit(1);
    }
    if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
        log(Fp, "pid file already locked");
    }
}
```

```

        exit(1);
    }

    log(Fp, "locking file");
    if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
        log(Fp, "lock failed");
        exit(1);
    }
    fprintf(Tfp, "%d", getpid());
    fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
    handlepoll();
    pause();
    fclose(Tfp);
    fclose(Fp);
}

handlepoll()
{
    int pfd; /* file descriptor for incoming pipe */
    int sfd; /* file descriptor for outgoing pipe */
    struct sacmsg sacmsg; /* incoming message */
    struct pmmsg pmmsg; /* outgoing message */

/*
 * open pipe for incoming messages from the sac
 */
    pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
    if (pfd < 0) {
        log(Fp, "_pmpipe open failed");
        exit(1);
    }

/*
 * open pipe for outgoing messages to the sac
 */
    sfd = open("../_sacpipe", O_WRONLY);
    if (sfd < 0) {
        log(Fp, "_sacpipe open failed");
        exit(1);
    }

/*
 * start to build a return message; we only support class 1 messages
 */
    strcpy(pmmsg.pm_tag, Tag);
    pmmsg.pm_size = 0;
    pmmsg.pm_maxclass = 1;

/*
 * keep responding to messages from the sac
 */
    for (;;) {
        if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
            log(Fp, "_pmpipe read failed");
            exit(1);
        }
    }
}

/*

```

saf(1M)

```
* determine the message type and respond appropriately
*/
switch (sacmsg.sc_type) {
    case SC_STATUS:
        log(Fp, "Got SC_STATUS message");
        pmmsg.pm_type = PM_STATUS;
        pmmsg.pm_state = State;
        break;
    case SC_ENABLE:
        /*note internal state change below*/
        log(Fp, "Got SC_ENABLE message");
        pmmsg.pm_type = PM_STATUS;

        pmmsg.pm_state = State;
        break;
    case SC_DISABLE:
        /*note internal state change below*/
        log(Fp, "Got SC_DISABLE message");
        pmmsg.pm_type = PM_STATUS;
        State = PM_DISABLED;
        pmmsg.pm_state = State;
        break;
    case SC_READDB:
        /*
         * if this were a fully functional port
         * monitor it would read _pmtab here
         * and take appropriate action
         */
        log(Fp, "Got SC_READDB message");
        pmmsg.pm_type = PM_STATUS;
        pmmsg.pm_state = State;
        break;
    default:
        sprintf(Scratch, "Got unknown message <%d>",
            sacmsg.sc_type);
        log(Fp, Scratch);
        pmmsg.pm_type = PM_UNKNOWN;
        pmmsg.pm_state = State;
        break;
}

/*
 * send back a response to the poll
 * indicating current state
 */
if (write(sfd, &pmmsg, sizeof(pmmsg)) != sizeof(pmmsg))
    log(Fp, "sanity response failed");
}

/*
 * general logging function
 */
log(fp, msg)
    FILE *fp;
    char *msg;
{
    fprintf(fp, "%d; %s\n", getpid(), msg);
}
```

The sac.h Header File

```
    fflush(fp);
}
```

The following example shows the sac.h header file.

```
/* length in bytes of a utmpx id */
#define IDLEN 4
/* wild character for utmpx ids */
#define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
#define PMTAGSIZE 14
/*

# define E_PMNOTRUN 8 /* port monitor is not running */
# define E_RECOVER 9
/* in recovery */
```

Directory Structure

This section gives a description of the SAF files and directories.

<code>/etc/saf/_sysconfig</code>	The per-system configuration script.
<code>/etc/saf/_sactab</code>	The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.
<code>/etc/saf/pmtag</code>	The home directory for port monitor <i>pmtag</i> .
<code>/etc/saf/pmtag/_config</code>	The per-port monitor configuration script for port monitor <i>pmtag</i> .
<code>/etc/saf/pmtag/_pmtab</code>	Port monitor <i>pmtag</i> 's administrative file. Contains information about the services for which <i>pmtag</i> is responsible.
<code>/etc/saf/pmtag/svctag</code>	The file in which the per-service configuration script for service <i>svctag</i> (available through port monitor <i>pmtag</i>) is placed.

saf(1M)

/etc/saf/pmtag/_pid The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file. */etc/saf/pmtag/_pmpipe* The file in which the port monitor receives messages from the SAC and *./_sacpipe* and sends return messages to the SAC. */var/saf/_log* The SAC's log file. */var/saf/pmtag* The directory for files created by port monitor *pmtag*, for example its log file.

LIST OF COMMANDS

The following administrative commands relate to SAF.

sacadm(1M) port monitor administrative command
pmadm(1M) service administration command

sar(1M)

NAME	sar, sa1, sa2, sadc – system activity report package
SYNOPSIS	<pre>/usr/lib/sa/sadc [t n] [ofile] /usr/lib/sa/sa1 [t n] /usr/lib/sa/sa2 [-aAbcdgkmpqruvw] [-e time] [-f filename] [-i sec] [-s time]</pre>
DESCRIPTION	<p>System activity data can be accessed at the special request of a user (see <code>sar(1)</code>) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use <code>iostat(1M)</code>, <code>sar(1)</code>, or <code>vmstat(1M)</code>.</p> <p>See <i>Solaris Transition Guide</i> for device naming conventions for disks.</p> <p><code>sadc</code> and two shell procedures, <code>sa1</code> and <code>sa2</code>, are used to sample, save, and process this data.</p> <p><code>sadc</code>, the data collector, samples system data <i>n</i> times, with an interval of <i>t</i> seconds between samples, and writes in binary format to <i>ofile</i> or to standard output. The sampling interval <i>t</i> should be greater than 5 seconds; otherwise, the activity of <code>sadc</code> itself may affect the sample. If <i>t</i> and <i>n</i> are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the <code>/etc/init.d/perf</code> file writes the restart mark to the daily data file using the command entry:</p> <pre>su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa`date +%d`"</pre> <p>The shell script <code>sa1</code>, a variant of <code>sadc</code>, is used to collect and store data in the binary file <code>/var/adm/sa/sadd</code>, where <code>dd</code> is the current day. The arguments <i>t</i> and <i>n</i> cause records to be written <i>n</i> times at an interval of <i>t</i> seconds, or once if omitted. The following entries in <code>/var/spool/cron/crontabs/sys</code> will produce records every 20 minutes during working hours and hourly otherwise:</p> <pre>0 * * * 0-6 /usr/lib/sa/sa1 20,40 8-17 * * 1-5 /usr/lib/sa/sa1</pre> <p>See <code>crontab(1)</code> for details.</p> <p>The shell script <code>sa2</code>, a variant of <code>sar</code>, writes a daily report in the file <code>/var/adm/sa/sardd</code>. See the OPTIONS section in <code>sar(1)</code> for an explanation of the various options. The following entry in <code>/var/spool/cron/crontabs/sys</code> will report important activities hourly during the working day:</p> <pre>5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A</pre>

FILES /etc/init.d/perf

savecore(1M)

NAME	savecore – save a crash dump of the operating system
SYNOPSIS	<code>/usr/bin/savecore [-Lvd] [-f <i>dumpfile</i>] <i>directory</i></code>
DESCRIPTION	<p>The <code>savecore</code> utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the <code>/etc/init.d/savecore</code> file after the system boots, if <code>savecore</code> is enabled by way of <code>dumpadm(1M)</code>. <code>savecore</code> is enable on reboot by default.</p> <p>The <code>savecore</code> utility checks the crash dump to be certain it corresponds with the version of the operating system currently running. If it does, <code>savecore</code> saves the crash dump data in the file <code>directory/vmcore.n</code> and the kernel's namelist in <code>directory/unix.n</code>. The trailing <code>.n</code> in the pathnames is replaced by a number which grows every time <code>savecore</code> is run in that directory.</p> <p>Before writing out a crash dump, <code>savecore</code> reads a number from the file <code>directory/minfree</code>. This is the minimum number of kilobytes that must remain free on the file system containing <code>directory</code>. If after saving the crash dump the file system containing <code>directory</code> would have less free space the number of kilobytes specified in <code>minfree</code>, the crash dump is not saved. if the <code>minfree</code> file does not exist, <code>savecore</code> assumes a <code>minfree</code> value of 1 megabyte.</p> <p>The <code>savecore</code> utility also logs a reboot message using facility <code>LOG_AUTH</code> (see <code>syslog(3C)</code>). If the system crashed as a result of a panic, <code>savecore</code> logs the panic string too.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-L Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces <code>savecore</code> to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps may only be performed if you have configured your system to have a dedicated dump device using <code>dumpadm(1M)</code>.-v Verbose. Enables verbose error messages from <code>savecore</code>.-d Disregard dump header valid flag. Force <code>savecore</code> to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.-f <i>dumpfile</i> Attempt to save a crash dump from the specified file instead of from the system's current dump device. This option may be useful if the information stored on the dump device has been copied to an on-disk file by means of the <code>dd(1M)</code> command. <p><i>directory</i> Save the crash dump files to the specified directory. If no directory argument is present on the command line, <code>savecore</code> saves the crash dump files to the default <code>savecore</code> <i>directory</i>, configured by</p>

the dumpadm(1M) command.

BUGS If the dump device is also being used as a swap device, you must run savecore very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

sckmd(1M)

NAME sckmd – Sun Fire 15000 key management daemon

SYNOPSIS `/platform/SUNW,Sun-Fire-15000/lib/sckmd`

DESCRIPTION sckmd is a server process that resides on a Sun Fire 15000 domain. sckmd maintains the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure the communication between the Sun Fire 15000 System Controller (SC) and the cvcd(1M) and dcs(1M) daemons running on a Sun Fire 15000 domain. See ipsec(7P) for a description of Security Associations.

sckmd receives SAs from the SC and provides these SAs to the Security Association Databases (SADBs) using pf_key(7P).

sckmd normally starts up at system boot time. Each domain supports only one running sckmd process at a time.

FILES `/etc/inet/ipsecinit.conf` Configuration file for default system-wide IPsec policies

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	Sun Fire 15000 systems
Availability	SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr

SEE ALSO cvcd(1M), dcs(1M), ipsecconf(1M), attributes(5), authmd5h(7M), encr3des(7M), ipsec(7P), pf_key(7P)

Sun Enterprise 10000 SSP Reference Manual

Sun System Management Services (SMS) Reference Manual

NOTES IPsec is used by Sun Fire 15000 systems to secure the communication between the SC, and the cvcd(1M) and dcs(1M) daemons running on a domain. System-wide IPsec policies for these daemons are configured on a domain with ipsecconf(1M). Default policies are defined when the SUNWsckmr package is installed on a Sun Fire 15000 domain at OS install time.

Package SUNWsckmr configures default system-wide policies for cvcd(1M) and dcs(1M) by adding the following entries in `/etc/inet/ipsecinit.conf`:

```
{ dport sun-dr ulp tcp } permit { auth_alg md5 }
{ sport sun-dr ulp tcp } apply { auth_alg md5 sa unique }
{ dport cvc_hostd ulp tcp } permit { auth_alg md5 }
{ sport cvc_hostd ulp tcp } apply { auth_alg md5 sa unique }
```

The cvc_hostd service represents cvcd(1M) and the sun-dr service represents dcs(1M) in the preceding entries.

sckmd(1M)

These policies conform to the format defined by `ipsec(7P)` and require HMAC-MD5 authentication. See `authmd5h(7M)`.

System-wide policies for `cvcd(1M)` and `dcs(1M)` configured on a domain using `ipseconf(1M)` must match the IPsec policies defined for these services on the SC. On an SC, IPsec policies for these services are defined by the SMS key management daemon. Refer to `thekmd(1M)` man page in the *Sun System Management Services (SMS) Reference Manual*.

IPsec encryption or authentication with encryption can be enabled on the domain using the `encr_algs` and `encr_auth_algs` properties, as described in the `ipseconf(1M)` manual page. For example, the following `ipseconf(1M)` entries require Triple-DES and HMAC-MD5 authentication for the network console `cvcd(1M)` service:

```
{ dport cvc_hostd ulp tcp } permit { encr_algs 3des encr_auth_algs md5 }
{ sport cvc_hostd ulp tcp } apply { encr_algs 3des encr_auth_algs md5 sa unique }
```

See `encr3des(7M)` for Triple-DES authentication and `authmd5h(7M)` for HMAC-M5 authentication.

sendmail(1M)

NAME	sendmail – send mail over the internet						
SYNOPSIS	<pre>/usr/lib/sendmail [-ba] [-bD] [-bd] [-bi] [-bm] [-bp] [-bs] [-bt] [-bv] [-B <i>type</i>] [-C <i>file</i>] [-d <i>X</i>] [-F <i>fullname</i>] [-f <i>name</i>] [-G] [-h <i>N</i>] [-L <i>tag</i>] [-M <i>xvalue</i>] [-N<i>notifications</i>] [-n] [-O<i>option =value</i>] [-o <i>xvalue</i>] [-p <i>protocol</i>] [-q [<i>time</i>]] [-q <i>Xstring</i>] [-R <i>ret</i>] [-r <i>name</i>] [-t] [-U] [-V <i>envid</i>] [-v] [-X <i>logfile</i>] [<i>address...</i>]</pre>						
DESCRIPTION	<p>sendmail sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.</p> <p>sendmail is not intended as a user interface routine; other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages.</p> <p>With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.</p> <p>Local addresses are looked up in the local <code>aliases(4)</code> file, or in a name service as defined by the <code>nsswitch.conf(4)</code> file, and aliased appropriately. In addition, if there is a <code>.forward</code> file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about <code>.forward</code> files. Aliasing can be prevented by preceding the address with a backslash. Normally the sender is not included in alias expansions. For example, if "john" sends to "group", and "group" includes "john" in the expansion, then the message will not be delivered to "john". See the <code>MeToo</code> Processing Option for more information.</p> <p>There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. It is important to note that this cannot occur under any circumstances unless root owns <i>and</i> has exclusive write permission to the <code>/etc/mail/aliases*</code> files.</p> <p>If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a <code>dead.letter</code> file in the sender's home directory.</p>						
OPTIONS	<table><tr><td>-ba</td><td>Go into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages will be generated with a RETURN-LINEFEED at the end. Also, the <code>From:</code> and <code>Sender:</code> fields are examined for the name of the sender.</td></tr><tr><td>-bd</td><td>Run as a daemon in the background, waiting for incoming SMTP connections.</td></tr><tr><td>-bD</td><td>Run as a daemon in the foreground, waiting for incoming SMTP connections.</td></tr></table>	-ba	Go into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages will be generated with a RETURN-LINEFEED at the end. Also, the <code>From:</code> and <code>Sender:</code> fields are examined for the name of the sender.	-bd	Run as a daemon in the background, waiting for incoming SMTP connections.	-bD	Run as a daemon in the foreground, waiting for incoming SMTP connections.
-ba	Go into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages will be generated with a RETURN-LINEFEED at the end. Also, the <code>From:</code> and <code>Sender:</code> fields are examined for the name of the sender.						
-bd	Run as a daemon in the background, waiting for incoming SMTP connections.						
-bD	Run as a daemon in the foreground, waiting for incoming SMTP connections.						

-bi	Initialize the <code>aliases(4)</code> database. Root must own <i>and</i> have exclusive write permission to the <code>/etc/mail/aliases*</code> files for successful use of this option.
-bm	Deliver mail in the usual way (default).
-bp	Print a summary of the mail queue.
-bs	Use the SMTP protocol as described in RFC 821. This flag implies all the operations of the <code>-ba</code> flag that are compatible with SMTP.
-bt	Run in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.
-bv	Verify names only; do not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.
-B <i>type</i>	Indicate body <i>type</i> (7BIT or 8BITMIME).
-C <i>file</i>	Use alternate configuration file.
-d <i>X</i>	Set debugging value to <i>X</i> .
-F <i>fullname</i>	Set the full name of the sender.
-G	When accepting messages via the command line, indicate that they are for relay (gateway) submission. When this flag is set, <code>sendmail</code> might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. <code>sendmail</code> does not do any canonicalization in this mode.
-f <i>name</i>	Sets the name of the “from” person (that is, the sender of the mail).
-h <i>N</i>	Set the hop count to <i>N</i> . The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.
-L <i>tag</i>	Set the identifier used in <code>syslog</code> messages to the supplied <i>tag</i> .
-M <i>xvalue</i>	Set macro <i>x</i> to the specified <i>value</i> .
-n	Do not do aliasing.
-N <i>notifications</i>	Tag all addresses being sent as wanting the indicated <i>notifications</i> , which consists of the word “NEVER” or a comma-separated list of “SUCCESS”, “FAILURE”, and “DELAY” for successful delivery, failure and a message that is stuck in a queue somewhere. The default is “FAILURE,DELAY”.
-o <i>xvalue</i>	Set option <i>x</i> to the specified <i>value</i> . Processing Options are described below.
-O <i>option=value</i>	Set <i>option</i> to the specified <i>value</i> (for long from names). Processing Options are described below.

sendmail(1M)

-p <i>protocol</i>	Set the sending protocol. The <i>protocol</i> field can be in form <i>protocol: host</i> to set both the sending protocol and the sending host. For example: -pUUCP:uunet sets the sending <i>protocol</i> to UUCP and the sending host to uunet. (Some existing programs use -oM to set the <i>r</i> and <i>s</i> macros; this is equivalent to using -p).
-q[<i>time</i>]	Process saved messages in the queue at given intervals. If <i>time</i> is omitted, process the queue once. <i>time</i> is given as a tagged number, with <i>s</i> being seconds, <i>m</i> being minutes, <i>h</i> being hours, <i>d</i> being days, and <i>w</i> being weeks. For example, -q1h30m or -q90m would both set the timeout to one hour thirty minutes.
-q <i>Xstring</i>	Run the queue once, limiting the jobs to those matching <i>Xstring</i> . The key letter <i>X</i> can be: I to limit based on queue identifier. R to limit based on recipient. S to limit based on sender. A particular queued job is accepted if one of the corresponding addresses contains the indicated <i>string</i> .
-r <i>name</i>	An alternate and obsolete form of the -f flag.
-R <i>ret</i>	Identify the information you want returned if the message bounces; <i>ret</i> can be "HDRS" for headers only or "FULL" for headers plus body.
-t	Read message for recipients. To:, Cc:, and Bcc: lines will be scanned for people to send to. The Bcc: line will be deleted before transmission. Any addresses in the argument list will be suppressed. The NoRecipientAction Processing Option can be used to change the behaviour when no legal recipients are included in the message.
-U	Initial (user) submission. This should always be set when called from a user agent such as Mail or exmh and never be set when called by a network delivery agent such as rmail.
-v	Go into verbose mode. Alias expansions will be announced, and so forth.
-V <i>envid</i>	The indicated <i>envid</i> is passed with the envelope of the message and returned if the message bounces.
-X <i>logfile</i>	Log all traffic in and out of sendmail in the indicated <i>logfile</i> for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

Processing Options

There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

Oxvalue

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values *t*, *T*, *f*, or *F*; the default is *TRUE*), or a time interval.

The multiple character or long names use this syntax:

O Longname=argument

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

AliasFile (*Afile*)

Specify possible alias file(s).

AliasWait (*a N*)

If set, wait up to *N* minutes for an "@:@" entry to exist in the *aliases(4)* database before starting up. If it does not appear in *N* minutes, rebuild the database (if the *AutoRebuildAliases* option is also set) or issue a warning. Defaults to 10 minutes.

AllowBogusHELO

Allow a HELO SMTP command that does not include a host name. By default this option is disabled.

AutoRebuildAliases (*D*)

If set, rebuild the */etc/mail/aliases* database if necessary and possible. If this option is not set, *sendmail* will never rebuild the *aliases* database unless explicitly requested using *-bi*, or *newaliases(1)* is invoked. Note that in order for the database to be rebuilt, root must own *and* have exclusive write permission to the */etc/mail/aliases** files.

BlankSub (*Bc*)

Set the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to *SPACE* (that is, no change is made).

CheckAliases (*n*)

Validate the RHS of aliases when rebuilding the *aliases(4)* database.

sendmail(1M)

CheckpointInterval (CN)

Checkpoints the queue every *N* (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

ClassFactor (*zfact*)

The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` will be favored. Defaults to 1800.

ClientPortOptions

Set client SMTP options. The options are key=value pairs. Known keys are:

`Addr Address Mask` *Address Mask* defaults to `INADDR_ANY`. The address mask can be a numeric address in dot notation or a network name.

`Family` Address family (defaults to `INET`).

`Listen` Size of listen queue (defaults to 10).

`Port` Name/number of listening port (defaults to `smtp`).

`RcvBufSize` The size of the TCP/IP receive buffer.

`SndBufSize` The size of the TCP/IP send buffer.

`Modifier` Options (flags) for the daemon. Can be:

`h` Use name of interface for `HELO` command.

If `h` is set, the name corresponding to the outgoing interface address (whether chosen by means of the `Connection` parameter or the default) is used for the `HELO/EHLO` command.

ColonOkInAddr

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 "group" syntax. This option is on for version 5 and lower configuration files.

ConnectionCacheSize (kN)

The maximum number of open connections that will be cached at a time. The default is 1. This delays closing the current connection until either this invocation of `sendmail` needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

ConnectionCacheTimeout (K*timeout*)

The maximum amount of time a cached connection will be permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a

cached connection, it always sends a NOOP (no operation) command to check the connection; if this fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

ConnectionRateThrottle

The maximum number of connections permitted per second. After this many connections are accepted, further connections will be delayed. If not set or ≤ 0 , there is no limit.

ControlSocketName

Name of the control socket for daemon management. A running `sendmail` daemon can be controlled through this Unix domain socket. Available commands are: `help`, `restart`, `shutdown`, and `status`. The `status` command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket will be available. Note: for the sake of security, this Unix domain socket must be in a directory which is accessible only by root; `/var/spool/mqueue/.smcontrol` is recommended for the socket name.

DaemonPortOptions (Options)

Set server SMTP options. The options are *key=value* pairs. Known keys are:

Name	User-definable name for the daemon (defaults to "Daemon#"); used for error messages and logging.
Addr	Address mask (defaults INADDR_ANY) The address mask may be a numeric address in dot notation or a network name.
Family	Address family (defaults to INET)
Listen	Size of listen queue (defaults to 10)
Modifier	Options (flags) for the daemon; can be a sequence (without any delimiters) of: <ul style="list-style-type: none"> a Require authentication. b Bind to interface through which mail has been received. c Perform hostname canonification (.cf). f Require fully qualified hostname (.cf). h Use name of interface for HELO command. u Allow unqualified addresses (.cf). C Do not perform hostname canonification. E Disallow ETRN (see RFC 2476).

sendmail(1M)

Name	User-definable name for the daemon (defaults to Daemon#); used for error messages and logging.
Port	Name/number of listening port (defaults to smtp)
ReceiveSize	The size of the TCP/IP receive buffer.
SendSize	The size of the TCP/IP send buffer.

Note: sendmail will listen on a new socket for each occurrence of the `DaemonPortOptions` option in a configuration file.

DataFileBufferSize

Set the threshold, in bytes, before a memory-based queue data file becomes disk-based. The default is 4096 bytes

DeadLetterDrop

Defines the location of the system-wide `dead.letter` file, formerly hard-coded to `/var/tmp/dead.letter`. If this option is not set (the default), sendmail does not attempt to save to a system-wide `dead.letter` file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the `qf` file as it has in the past when the `dead.letter` file could not be opened.

DefaultCharSet

Set the default character set to use when converting unlabeled 8 bit input to MIME.

DefaultUser (*ggid*) or (*uuid*)

Set the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to 1. The value can also be given as a symbolic group or user name.

DeliveryMode (*dx*)

Deliver in mode *x*. Legal modes are:

- i* Deliver interactively (synchronously).
- b* Deliver in background (asynchronously).
- d* Deferred mode — database lookups are deferred until the actual queue run.
- q* Just queue the message (deliver during queue run).

Defaults to *b* if no option is specified, *i* if it is specified but given no argument (that is, `Od` is equivalent to `Odi`).

DialDelay

If a connection fails, wait this many seconds and try again. Zero means “do not retry”.

DontBlameSendmail

If set, override the file safety checks. This compromises system security and should not be used. See <http://www.sendmail.org/tips/DontBlameSendmail.html> for more information.

DontExpandCnames

If set, \$[... \$] lookups that do DNS-based lookups do not expand CNAME records.

DontInitGroups

If set, the `initgroups(3C)` routine will never be invoked. If you set this, agents run on behalf of users will only have their primary (`/etc/passwd`) group permissions.

DontProbeInterfaces

If set, `sendmail` will not insert the names and addresses of any local interfaces into the `$=w` class. If set, you must also include support for these addresses, otherwise mail to addresses in this list will bounce with a configuration error.

DontPruneRoutes (R)

If set, do not prune route-addr syntax addresses to the minimum possible.

DoubleBounceAddress

If an error occurs when sending an error message, send that "double bounce" error message to this address.

EightBitMode (8)

Use 8-bit data handling. This option requires one of the following keys. The key can be selected by using just the first character, but using the full word is better for clarity.

- `mimify` Do any necessary conversion of 8BITMIME to 7-bit.
- `pass` Pass unlabeled 8-bit input through as is.
- `strict` Reject unlabeled 8-bit input.

ErrorHeader (Efile/message)

Append error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or `NULL`, or if it names a file which does not exist or which is not readable, no message is printed.

ErrorMode (ex)

Dispose of errors using mode *x*. The values for *x* are:

- `e` Mail back errors and give 0 exit status always.
- `m` Mail back errors.
- `p` Print error messages (default).
- `q` No messages, just give exit status.
- `w` Write back errors (mail if user not logged in).

FallbackMXhost (vfallbackhost)

If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

sendmail(1M)

ForkEachJob (Y)

If set, deliver each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

ForwardPath (J*path*)

Set the path for searching for users' `.forward` files. The default is `$z/.forward`. Some sites that use the automounter may prefer to change this to `/var/forward/$u` to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; `sendmail` stops at the first file it can successfully and safely open. For example, `/var/forward/$u:$z/.forward` will search first in `/var/forward/username` and then in `~username/.forward` (but only if the first file does not exist). Refer to the NOTES section for more information.

HelpFile (H*file*)

Specify the help file for SMTP.

HoldExpensive (c)

If an outgoing mailer is marked as being expensive, don't connect immediately.

HostsFile

Set the file to use when doing "file" type access of host names.

HostStatusDirectory

If set, host status is kept on disk between `sendmail` runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

IgnoreDots (i)

Ignore dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

LogLevel (Ln)

Set the default log level to *n*. Defaults to 9.

(M*x value*)

Set the macro *x* to *value*. This is intended only for use from the command line.

MatchGECOS (G)

Try to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

MaxDaemonChildren

The maximum number of children the daemon will permit. After this number, connections are rejected. If not set or ≤ 0 , there is no limit.

MaxHopCount (h*N*)

The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to 25.

MaxMessageSize

The maximum size of messages that will be accepted (in bytes).

MaxMimeHeaderLength=M[/N]

Sets the maximum length of certain MIME header field values to M characters. For some of these headers which take parameters, the maximum length of each parameter is set to N if specified. If $/N$ is not specified, one half of M will be used. By default, these values are 0, meaning no checks are done.

MaxQueueRunSize

If set, limit the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

MeToo (M)

Send to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage

If set, allow no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

MinFreeBlocks (bN/M)

Insist on at least N blocks free on the file system that holds the queue files before accepting email via SMTP. If there is insufficient space, `sendmail` gives a 452 response to the MAIL command. This invites the sender to try again later. The optional M is a maximum message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

MinQueueAge

The amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

MustQuoteChars

Characters to be quoted in a full name phrase. `&`, `;`, `\`, `()` `[]` are quoted automatically.

NoRecipientAction

Set action if there are no legal recipient files in the message. The legal values are:

<code>add-apparently-to</code>	Add an <code>Apparently-to:</code> header with all the known recipients (which may expose blind recipients).
<code>add-bcc</code>	Add an empty <code>Bcc:</code> header.
<code>add-to</code>	Add a <code>To:</code> header with all the known recipients (which may expose blind recipients).
<code>add-to-undisclosed</code>	Add a <code>To: undisclosed-recipients:</code> header.
<code>none</code>	Do nothing, leave the message as it is.

sendmail(1M)

OldStyleHeaders (o)

Assume that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it will be assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

OperatorChars or \$o

Defines the list of characters that can be used to separate the components of an address into tokens.

PidFile

Filename of the pid file. The default is `/var/run/sendmail.pid`. The filename is macro-expanded before it is opened.

PostmasterCopy (Ppostmaster)

If set, copies of error messages will be sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

PrivacyOptions (popt,opt,...)

Set privacy options. Privacy is really a misnomer; many of these are just a way of insisting on stricter adherence to the SMTP protocol.

The goaway pseudo-flag sets all flags except `restrictmailq` and `restrictqrun`. If `mailq` is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. `authwarnings` add warnings about various conditions that may indicate attempts to spoof the mail system, such as using a non-standard queue directory.

The options can be selected from:

<code>authwarnings</code>	Put X-Authentication-Warning: headers in messages.
<code>goaway</code>	Disallow essentially all SMTP status queries.
<code>needexpnhelo</code>	Insist on HELO or EHLO command before EXPN.
<code>needmailhelo</code>	Insist on HELO or EHLO command before MAIL.
<code>needvrfyhelo</code>	Insist on HELO or EHLO command before VRFY.
<code>noetrn</code>	Disallow ETRN entirely.
<code>noexpn</code>	Disallow EXPN entirely.
<code>noreceipts</code>	Prevent return receipts.
<code>nobodyreturn</code>	Do not return the body of a message with DSNs.
<code>novrfy</code>	Disallow VRFY entirely.
<code>public</code>	Allow open access.

<code>restrictmailq</code>	Restrict mailq command.
<code>restrictqrun</code>	Restrict -q command line flag.
<code>ProcessTitlePrefix</code> <i>string</i>	Prefix the process title shown on “/usr/ucb/ps auxww” listings with <i>string</i> . The string will be macro processed.
<code>QueueDirectory</code> (<i>Qdir</i>)	Use the named <i>dir</i> as the queue directory.
<code>QueueFactor</code> (<i>qfactor</i>)	Use <i>factor</i> as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (<i>xflag</i>) to determine the maximum message priority that will be sent. Defaults to 600000.
<code>QueueLA</code> (<i>xLA</i>)	When the system load average exceeds <i>LA</i> , just queue messages (that is, do not try to send them). Defaults to eight times the number of processors online when sendmail starts.
<code>QueueSortOrder</code>	Select the queue sort algorithm. The default value is <code>Priority</code> . Other values are <code>Host</code> , <code>Time</code> , or <code>Filename</code> .
<code>QueueTimeout</code> (<i>Trtime/wtime</i>)	Set the queue timeout to <i>rtime</i> . After this interval, messages that have not been successfully sent will be returned to the sender. Defaults to five days (5d). The optional <i>wtime</i> is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.
<code>RecipientFactor</code> (<i>yfact</i>)	The indicated factor <i>fact</i> is added to the priority (thus <i>lowering</i> the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.
<code>RefuseLA</code> (<i>xLA</i>)	When the system load average exceeds <i>LA</i> , refuse incoming SMTP connections. Defaults to 12 times the number of processors online when sendmail starts.
<code>RemoteMode</code> (> [<i>RemoteMboxHost</i>])	If <i>RemoteMboxHost</i> is specified, then <i>remote-mode</i> is enabled using this host. If <i>RemoteMboxHost</i> is not specified, and if /var/mail is remotely mounted, then <i>remote-mode</i> is enabled using the remote mount host. If <i>RemoteMboxHost</i> is not specified and /var/mail is locally mounted, then <i>remote-mode</i> is disabled. When <i>remote-mode</i> is enabled, all outgoing messages are sent through that server.
<code>ResolverOptions</code> (<i>I</i>)	Tune DNS lookups.

sendmail(1M)

RetryFactor (*Zfact*)

The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority will be decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

RrtImpliesDsn

If this option is set, a "Return-Receipt-To:" header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

RunAsUser

If set, become this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

SafeFileEnvironment

If set, sendmail will do a chroot into this directory before writing files.

SaveFromLine (*f*)

Save Unix-style From lines at the front of headers. Normally they are assumed redundant and discarded.

SendMimeErrors (*j*)

If set, send error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, sendmail does not return the DSN keyword in response to an EHLO and does not do Delivery Status Notification processing as described in RFC 1891.

ServiceSwitchFile

Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

SevenBitInput (*7*)

Strip input to seven bits for compatibility with old systems. This should not be necessary.

SingleLineFromHeader

If set, From: lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery

If this option and the HostStatusDirectory option are both set, use single thread deliveries to other hosts.

SmtgreetingMessage or *\$e*

The initial SMTP greeting message.

StatusFile (*\$file*)

Log statistics in the named file.

SuperSafe (*s*)

Be super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. sendmail always instantiates the queue file before returning control to the client under any circumstances.

TempFileMode (*Fmode*)

The file mode for queue files.

Timeout (*rtimeouts*)

Timeout reads after `t` time interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no *keyword=* part will set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

command

command read [1h, 5m]

connect

initial connect [0, unspecified]

control

complete control socket transaction [2m, none]

datablock

data block read [1h, 3m]

datafinal

reply to final "." in data [1h, 10m]

datainit

reply to DATA command [5m, 2m]

fileopen

file open [60sec, none]

helo

reply to HELO or EHLO command [5m, none]

hoststatus

host retry [30m, unspecified]

iconnect

first attempt to connect to a host [0, unspecified]

ident

IDENT protocol timeout [30s, none]

initial

wait for initial greeting message [5m, 5m]

mail

reply to MAIL command [10m, 5m]

misc

reply to NOOP and VERB commands [2m, none]

queuereturn

undeliverable message returned [5d]

sendmail(1M)

`queuwarn`
deferred warning [4h]

`quit`
reply to QUIT command [2m, none]

`rcpt`
reply to RCPT command [1h, 5m]

`resolver.retrans`
Resolver's retransmission time interval (in seconds) [varies]. Sets both `Timeout.resolver.retrans.first` and `Timeout.resolver.retrans.normal`.

`resolver.retrans.first`
Resolver's retransmission time interval (in seconds) for the first attempt to deliver a message [varies].

`resolver.retrans.normal`
Resolver's retransmission time interval (in seconds) for all look-ups except the first delivery attempt [varies].

`resolver.retry`
Number of times to retransmit a resolver query [varies]. Sets both `Timeout.resolver.retry.first` and `Timeout.resolver.retry.normal`.

`resolver.retry.first`
Number of times to retransmit a resolver query for the first attempt to deliver a message [varies].

`resolver.retry.normal`
Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

`rset`
reply to RSET command [5m, none]

`TimeZoneSpec (tzinfo)`
Set the local time zone info to *tzinfo*, for example, "PST8PDT ". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

`TrustedUser`
The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

`TryNullMXList (w)`
If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the

mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes `sendmail` to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.

`UnixFromLine` or `$1`

The "From " line used when sending to files or programs.

`UnsafeGroupWrites`

If set, group-writable `:include:` and `.forward` files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.

`UseErrorsTo` (1)

If there is an `Errors-To:` header, send error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes `sendmail` to violate RFC 1123.

`UserDatabaseSpec` (U)

Defines the name and location of the file containing User Database information.

`Verbose` (v)

Run in verbose mode. If this is set, `sendmail` adjusts the `HoldExpensive` and `DeliveryMode` options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The `Verbose` option should *never* be set in the configuration file; it is intended for command line use only.

`XscriptFileBufferSize`

Set the threshold, in bytes, before a memory-based queue transcript file becomes disk-based. The default is 4096 bytes.

All options can be specified on the command line using the `-oflag`, but most will cause `sendmail` to relinquish its setuid permissions. The options that will not cause this are `b`, `d`, `e`, `E`, `i`, `L`, `m`, `o`, `p`, `r`, `s`, `v`, `C`, and `7`. Also considered "safe" is `M` (define macro) when defining the `r` or `s` macros.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep `sendmail` from suppressing the blanks from between arguments.

If invoked as `newaliases`, `sendmail` rebuilds the alias database, so long as the `/etc/mail/aliases*` files are owned by root *and* root has exclusive write permission. If invoked as `mailq`, `sendmail` prints the contents of the mail queue.

OPERANDS

address address of an intended recipient of the message being sent.

USAGE

See `largefile(5)` for the description of the behavior of `sendmail` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

sendmail(1M)

EXIT STATUS sendmail returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

EX_OK	Successful completion on all addresses.
EX_NOUSER	User name not recognized.
EX_UNAVAILABLE	Catchall. Necessary resources were not available.
EX_SYNTAX	Syntax error in address.
EX_SOFTWARE	Internal software error, including bad arguments.
EX_OSERR	Temporary operating system error, such as “cannot fork”.
EX_NOHOST	Host name not recognized.
EX_TEMPFAIL	Message could not be sent immediately, but was queued.

FILES

<code>dead.letter</code>	unmailable text
<code>/etc/mail/aliases</code>	mail aliases file (ASCII)
<code>/etc/mail/aliases.dir</code>	database of mail aliases (binary)
<code>/etc/mail/aliases.pag</code>	database of mail aliases (binary)
<code>/etc/mail/sendmail.cf</code>	defines environment for sendmail
<code>/etc/mail/sendmail.cf</code>	defines environment for sendmail
<code>/var/spool/mqueue/*</code>	temp files and queued mail
<code>~/.forward</code>	list of recipients for forwarding messages

Costales, Bryan with Eric Allman, *sendmail, Second Edition*, O'Reilly & Associates, Inc., 1997.

- NOTES** The `sendmail` program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see `check-hostname(1M)`).
- The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to `/etc/mail` and `/var/spool/mqueue` has been restricted.
- Security restrictions have been placed users using `.forward` files to pipe mail to a program or redirect mail to a file. The default shell (as listed in `/etc/passwd`) of these users must be listed in `/etc/shells`. This restriction does not affect mail that is being redirected to another alias.
- Additional restrictions have been put in place on `.forward` and `:include:` files. These files and the directory structure that they are placed in cannot be group- or world-writable (see `check-permissions(1M)`).
- If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the `DontProbeInterfaces` option to enable delivery to those destinations. In its default startup behavior, `sendmail` probes each interface and adds an interface's IP address(es), as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with `localhost` as the MX value. If this is not the result you want, enable `DontProbeInterfaces`.

setuname(1M)

NAME setuname – change machine information

SYNOPSIS **setuname** [-t] [-n *node*] [-s *name*]

DESCRIPTION The *setuname* utility changes the parameter value for the system name and node name. Each parameter can be changed using *setuname* and the appropriate option.

Either or both the *-s* and *-n* options must be given when invoking *setuname*.

The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.

OPTIONS The following options are supported:

- t Temporary change. No attempt will be made to create a permanent change.
- n *node* Changes the node name. *node* specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.
- s *name* Changes the system name. *name* specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu (32-bit) SUNWcsxu (64-bit)

SEE ALSO *attributes(5)*

NOTES *setuname* attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.

NAME sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon

SYNOPSIS `sf880drd`

DESCRIPTION The Sun Fire 880 Dynamic Reconfiguration daemon, `sf880drd`, is part of the PCI and system bus hotplug framework. `sf880drd` starts at boot time. It has no configuration options and does not report any system status.

`sf880drd` implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.

FILES `/usr/platform/SUNW,Sun-Fire-880/lib/sf880drd`

share(1M)

NAME	share – make local resource available for mounting by remote systems														
SYNOPSIS	share [-F <i>FSType</i>] [-o <i>specific_options</i>] [-d <i>description</i>] [<i>pathname</i>]														
DESCRIPTION	The share command exports, or makes a resource available for mounting, through a remote file system of type <i>FSType</i> . If the option -F <i>FSType</i> is omitted, the first file system type listed in /etc/dfs/fstypes is used as default. For a description of NFS specific options, see share_nfs(1M). <i>pathname</i> is the pathname of the directory to be shared. When invoked with no arguments, share displays all shared file systems.														
OPTIONS	<table border="0"> <tr> <td style="vertical-align: top;">-F <i>FSType</i></td> <td>Specify the filesystem type.</td> </tr> <tr> <td style="vertical-align: top;">-o <i>specific_options</i></td> <td>The <i>specific_options</i> are used to control access of the shared resource. (See share_nfs(1M) for the NFS specific options.) They may be any of the following:</td> </tr> <tr> <td style="vertical-align: top;">rw</td> <td><i>pathname</i> is shared read/write to all clients. This is also the default behavior.</td> </tr> <tr> <td style="vertical-align: top;">rw=<i>client[:client]...</i></td> <td><i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i>.</td> </tr> <tr> <td style="vertical-align: top;">ro</td> <td><i>pathname</i> is shared read-only to all clients.</td> </tr> <tr> <td style="vertical-align: top;">ro=<i>client[:client]...</i></td> <td><i>pathname</i> is shared read-only only to the listed clients. No other systems can access <i>pathname</i>.</td> </tr> <tr> <td style="vertical-align: top;">-d <i>description</i></td> <td>The -d flag may be used to provide a description of the resource being shared.</td> </tr> </table>	-F <i>FSType</i>	Specify the filesystem type.	-o <i>specific_options</i>	The <i>specific_options</i> are used to control access of the shared resource. (See share_nfs(1M) for the NFS specific options.) They may be any of the following:	rw	<i>pathname</i> is shared read/write to all clients. This is also the default behavior.	rw= <i>client[:client]...</i>	<i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i> .	ro	<i>pathname</i> is shared read-only to all clients.	ro= <i>client[:client]...</i>	<i>pathname</i> is shared read-only only to the listed clients. No other systems can access <i>pathname</i> .	-d <i>description</i>	The -d flag may be used to provide a description of the resource being shared.
-F <i>FSType</i>	Specify the filesystem type.														
-o <i>specific_options</i>	The <i>specific_options</i> are used to control access of the shared resource. (See share_nfs(1M) for the NFS specific options.) They may be any of the following:														
rw	<i>pathname</i> is shared read/write to all clients. This is also the default behavior.														
rw= <i>client[:client]...</i>	<i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i> .														
ro	<i>pathname</i> is shared read-only to all clients.														
ro= <i>client[:client]...</i>	<i>pathname</i> is shared read-only only to the listed clients. No other systems can access <i>pathname</i> .														
-d <i>description</i>	The -d flag may be used to provide a description of the resource being shared.														
EXAMPLES	<p>EXAMPLE 1 A sample of using share command.</p> <p>This line will share the /disk file system read-only at boot time.</p> <pre>share -F nfs -o ro /disk</pre>														
FILES	<table border="0"> <tr> <td>/etc/dfs/dfstab</td> <td>list of share commands to be executed at boot time</td> </tr> <tr> <td>/etc/dfs/fstypes</td> <td>list of file system types, NFS by default</td> </tr> <tr> <td>/etc/dfs/sharetab</td> <td>system record of shared file systems</td> </tr> </table>	/etc/dfs/dfstab	list of share commands to be executed at boot time	/etc/dfs/fstypes	list of file system types, NFS by default	/etc/dfs/sharetab	system record of shared file systems								
/etc/dfs/dfstab	list of share commands to be executed at boot time														
/etc/dfs/fstypes	list of file system types, NFS by default

ATTRIBUTES	See attributes(5) for descriptions of the following attributes:														

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO mountd(1M), nfsd(1M), share_nfs(1M), shareall(1M), unshare(1M), attributes(5)

NOTES Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the `share` command used to be invoked as `exportfs(1B)` or `/usr/sbin/exportfs`.

If `share` commands are invoked multiple times on the same filesystem, the last `share` invocation supersedes the previous—the options set by the last `share` command replace the old options. For example, if read-write permission was given to `usera` on `/somefs`, then to give read-write permission also to `userb` on `/somefs`:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

shareall(1M)

NAME shareall, unshareall – share, unshare multiple resources

SYNOPSIS **shareall** [-F *FSType* [, *FSType*...]] [- | *file*]
unshareall [-F *FSType* [, *FSType*...]]

DESCRIPTION When used with no arguments, **shareall** shares all resources from *file*, which contains a list of **share** command lines. If the operand is a hyphen (-), then the **share** command lines are obtained from the standard input. Otherwise, if neither a *file* nor a hyphen is specified, then the file */etc/dfs/dfstab* is used as the default.

Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F.

unshareall unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.

OPTIONS -F *FSType* Specify file system type. Defaults to the first entry in */etc/dfs/fstypes*.

FILES */etc/dfs/dfstab*

ATTRIBUTES See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO **share(1M)**, **unshare(1M)**, **attributes(5)**

NAME	share_nfs – make local NFS file systems available for mounting by remote systems
SYNOPSIS	share [-d <i>description</i>] [-F nfs] [-o <i>specific_options</i>] <i>pathname</i>
DESCRIPTION	<p>The share utility makes local file systems available for mounting by remote systems.</p> <p>If no argument is specified, then share displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.</p>
OPTIONS	<p>The following options are supported:</p> <p>-d <i>description</i> Provide a comment that describes the file system to be shared.</p> <p>-F nfs Share NFS file system type.</p> <p>-o <i>specific_options</i> Specify <i>specific_options</i> in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If <i>specific_options</i> is not specified, then by default sharing will be read-write to all clients. <i>specific_options</i> can be any combination of the following:</p> <p>aclok Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.</p> <p>anon=<i>uid</i> Set <i>uid</i> to be the effective user ID of unknown users. By default, unknown users are given the effective user ID UID_NOBODY. If <i>uid</i> is set to -1, access is denied.</p> <p>index=<i>file</i> Load <i>file</i> rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.</p> <p>kerberos This option has been deprecated in favor of the <i>sec=krb4</i> option.</p> <p>log=<i>tag</i> Enables NFS server logging for the specified file system. The optional <i>tag</i> determines the location of the related log files. The <i>tag</i> is defined in</p>

`etc/nfs/nfslog.conf`. If no tag is specified, the default values associated with the "global" tag in `etc/nfs/nfslog.conf` will be used.

nosub

Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the `nosub` option on server *fooey* then a NFS client will not be able to do:

```
mount -F nfs fooey:/export/home/mnt
```

nosuid

By default, clients are allowed to create files on the shared file system with the `setuid` or `setgid` mode enabled. Specifying `nosuid` causes the server file system to silently ignore any attempt to enable the `setuid` or `setgid` mode bits.

public

Moves the location of the public file handle from root (`/`) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the `public` option.

ro

Sharing will be read-only to all clients.

ro=*access_list*

Sharing will be read-only to the clients listed in *access_list*; overrides the `rw` suboption for the clients specified. See *access_list* below.

root=*access_list*

Only root users from the hosts specified in *access_list* will have root access. See *access_list* below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the `anon=uid` option described above). Netgroups can be used if the file system shared is using UNIX authentication (`AUTH_SYS`).

rw

Sharing will be read-write to all clients.

rw=access_list

Sharing will be read-write to the clients listed in *access_list*; overrides the *ro* suboption for the clients specified. See *access_list* below.

sec=mode[:mode]. . .

Sharing will use one or more of the specified security modes. The *mode* in the *sec=mode* option must be a node name supported on the client. If the *sec=* option is not specified, the default security mode used is `AUTH_SYS`. Multiple *sec=* options can be specified on the command line, although each mode can appear only once. The security modes are defined in `nfssec(5)`.

Each *sec=* option specifies modes that apply to any subsequent *window=*, *rw*, *ro*, *rw=*, *ro=* and *root=* options that are provided before another *sec=* option. Each additional *sec=* resets the security mode context, so that more *window=*, *rw*, *ro*, *rw=*, *ro=* and *root=* options can be supplied for additional modes.

sec=none

If the option *sec=none* is specified when the client uses `AUTH_NONE`, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the *anon=uid* option for a description of how unauthenticated requests are handled.

secure

This option has been deprecated in favor of the *sec=dh* option.

window=value

When sharing with *sec=dh* or *sec=krb4* set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server will allow. If a credential arrives with a life time larger than what is allowed, the NFS server will reject the request. The default value is 30000 seconds (8.3 hours).

access_list

The *access_list* argument is a colon-separated list whose components may be any number of the following:

share_nfs(1M)

hostname	<p>The name of a host. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname must be represented as a fully qualified DNS or LDAP name.</p>
netgroup	<p>A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.</p>
domain name suffix	<p>To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the <code>/etc/nsswitch.conf</code> must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,</p> <pre>NIS or NIS+ 129.144.45.9 --> "myhost DNS or LDAP 129.144.45.9 --> "myhost.mydomain.mycompany.com"</pre> <p>The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,</p> <pre>rw=.mydomain.mycompany.com</pre> <p>A single dot can be used to match a hostname with no suffix. For example,</p> <pre>rw=.</pre> <p>will match "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.</p>
network	<p>The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it will be converted to a dotted address by <code>getnetbyname(3SOCKET)</code>. For example,</p> <pre>=@mynet</pre> <p>would be equivalent to:</p>

share_nfs(1M)

=@129.144 or =@129.144.0.0The network prefix assumes an octet aligned netmask determined from the zero octets in the low-order part of the address. In the case where network prefixes are not byte-aligned, the syntax will allow a mask length to be specified explicitly following a slash (/) delimiter. For example,

=@mynet/17 or rw=@129.144.132/17where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

A prefixed minus sign (-) denies access to that component of *access_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

```
rw=-terra:engineeringwill deny access to terra but
```

```
rw=engineering:-terrawill grant access to terra.
```

OPERANDS The following operands are supported:

pathname The pathname of the file system to be shared.

EXAMPLES **EXAMPLE 1** Sharing A File System With Logging Enabled

The following example shows the /export file system shared with logging enabled:

```
example% share -o log /export
```

The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in /etc/nfs/nfslog.conf. Note that the nfslogd(1M) daemon will run only if at least one file system entry in /etc/dfs/dfstab is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line will not start the nfslogd(1M).

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

/etc/dfs/fstypes	list of system types, NFS by default
/etc/dfs/sharetab	system record of shared file systems
/etc/nfs/nfslogtab	system record of logged file systems
/etc/nfs/nfslog.conf	logging configuration file

share_nfs(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `mount(1M)`, `mountd(1M)`, `nfsd(1M)`, `nfslogd(1M)`, `share(1M)`, `unshare(1M)`, `getnetbyname(3SOCKET)`, `nfslog.conf(4)`, `netgroup(4)`, `attributes(5)`, `nfssec(5)`

NOTES If the `sec=` option is presented at least once, all uses of the `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options must come after the first `sec=` option. If the `sec=` option is not presented, then `sec=sys` is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the `AUTH_SYS` security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /var will grant read-write access to any host using
AUTH_SYS, but

share -F nfs -o sec=dh /var will grant no access to clients that use AUTH_SYS.
```

Unlike previous implementations of `share_nfs(1M)`, access checking for the `window=`, `rw`, `ro`, `rw=`, and `ro=` options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the `ro=` and `rw=` options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for `hosta` (albeit on each NFS request) to side-step the stronger controls of `AUTH_DES`. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids `AUTH_DES` will only get read-only access. In general, multiple security modes per `share` command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If `rw=`, and `ro=` options are specified in the same `sec=` clause, and a client is in both lists, the order of the two options determines the access the client gets. If client `hosta` is in two `netgroups - group1` and `group2` - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example `hosta` would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a `sec=` clause, both the `ro` and `rw=` options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the `ro=` and `rw` options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The `ro=` and `rw=` options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_SYS` is guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_DES` and `AUTH_KERB` is guaranteed to work over any transport provider.

There are no interactions between the `root=` option and the `rw`, `ro`, `rw=`, and `ro=` options. Putting a host in the `root` list does not override the semantics of the other options. The access the host gets is the same as when the `root=` options is absent. For example, the following `share` command will deny access to `hostb`:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following will give read-only permissions to `hostb`:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following will give read-write permissions to `hostb`:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `share` command will result in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

Note that an NFS mount of `server:/export/foo` will result in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file will share the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

Note that the same command entered from the command line will not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if

share_nfs(1M)

there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

NAME showmount – show all remote mounts

SYNOPSIS `/usr/sbin/showmount [-ade] [hostname]`

DESCRIPTION showmount lists all the clients that have remotely mounted a filesystem from *host*. This information is maintained by the mountd(1M) server on *host*, and is saved across crashes in the file `/etc/rmtab`. The default value for *host* is the value returned by `hostname(1)`.

OPTIONS

- a Print all remote mounts in the format:

```
hostname : directory
```

where *hostname* is the name of the client, and *directory* is the root of the file system that has been mounted.
- d List directories that have been remotely mounted by clients.
- e Print the list of shared file systems.

FILES `/etc/rmtab`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `hostname(1)`, `mountd(1M)`, `attributes(5)`

Solaris 8 Advanced Installation Guide

BUGS If a client crashes, its entry will not be removed from the list of remote mounts on the server.

showrev(1M)

NAME showrev – show machine and software revision information

SYNOPSIS `/usr/bin/showrev [-a] [-p] [-w] [-c command] [-s hostname]`

DESCRIPTION showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.

If a command is supplied with the -c option, showrev shows the PATH and LD_LIBRARY_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.

OPTIONS The following options are supported:

- a Print all system revision information available. Window system and patch information are added.
- p Print only the revision information about patches.
- w Print only the OpenWindows revision information.
- c *command* Print the revision information about *command*.
- s *hostname* Perform this operation on the specified *hostname*. The -s operation completes correctly only when *hostname* is running Solaris 2.5 or compatible versions.

OUTPUT Varies, based on flags passed. If no flags are passed, output similar to the following appears:

```
Hostname: system1
Hostid: 7233808e
Release: 5.4
Kernel architecture: sun4m
Application architecture: sparc
Hardware provider: Sun_Microsystems
Domain: a.network.COM
Kernel version: SunOS 5.4 generic July 1994
```

EXIT STATUS The following error values are returned:

- 0 Successful completion.
- >0 An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmc

showrev(1M)

SEE ALSO arch(1), ldd(1), mcs(1), sum(1), patchadd(1M), attributes(5)

BUGS For the `-s` option to work when `hostname` is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on `hostname`.

shutdown(1M)

NAME	shutdown – shut down system, change system state										
SYNOPSIS	<code>/usr/sbin/shutdown</code> [-y] [-g <i>grace-period</i>] [-i <i>init-state</i>] [<i>message</i>]										
DESCRIPTION	<p>shutdown is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.</p> <p>By default, shutdown brings the system to a state where only the console has access to the operating system. This state is called single-user.</p> <p>Before starting to shut down daemons and killing processes, shutdown sends a warning message and, by default, a final message asking for confirmation. <i>message</i> is a string that is sent out following the standard warning message "The system will be shut down in . . ." If the string contains more than one word, it should be contained within single (') or double (") quotation marks.</p> <p>The warning message and the user provided <i>message</i> are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before shutdown begins. See EXAMPLES.</p> <p>System state definitions are:</p> <table><tr><td>state 0</td><td>Stop the operating system.</td></tr><tr><td>state 1</td><td>State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.</td></tr><tr><td>state s, S</td><td>State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.</td></tr><tr><td>state 5</td><td>Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.</td></tr><tr><td>state 6</td><td>Stop the operating system and reboot to the state defined by the <code>initdefault</code> entry in <code>/etc/inittab</code>. The rc6 procedure is called to perform this task.</td></tr></table>	state 0	Stop the operating system.	state 1	State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.	state s, S	State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.	state 5	Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.	state 6	Stop the operating system and reboot to the state defined by the <code>initdefault</code> entry in <code>/etc/inittab</code> . The rc6 procedure is called to perform this task.
state 0	Stop the operating system.										
state 1	State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.										
state s, S	State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.										
state 5	Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.										
state 6	Stop the operating system and reboot to the state defined by the <code>initdefault</code> entry in <code>/etc/inittab</code> . The rc6 procedure is called to perform this task.										
OPTIONS	<table><tr><td>-y</td><td>Pre-answer the confirmation question so the command can be run without user intervention.</td></tr><tr><td>-g <i>grace-period</i></td><td>Allow the super user to change the number of seconds from the 60-second default.</td></tr></table>	-y	Pre-answer the confirmation question so the command can be run without user intervention.	-g <i>grace-period</i>	Allow the super user to change the number of seconds from the 60-second default.						
-y	Pre-answer the confirmation question so the command can be run without user intervention.										
-g <i>grace-period</i>	Allow the super user to change the number of seconds from the 60-second default.										

shutdown(1M)

`-i init-state` If there are warnings, *init-state* specifies the state `init` is to be in. By default, system state 's' is used.

EXAMPLES

EXAMPLE 1 Using shutdown

In the following example, `shutdown` is being executed on host `foo` and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "==== disk replacement ====="
Shutdown started. Tue Jun 7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41. . .
The system will be shut down in 2 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41. . .
The system will be shut down in 1 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41. . .
The system will be shut down in 30 seconds
==== disk replacement =====
Do you want to continue? (y or n):
```

slpd(1M)

NAME	slpd – Service Location Protocol Daemon								
SYNOPSIS	<code>/usr/lib/inet/slpd [-f <i>configuration-file</i>]</code>								
DESCRIPTION	<p>The <code>slpd</code> daemon provides common server functionality for the Service Location Protocol (“SLP”) versions 1 and 2, as defined by IETF in <i>RFC 2165</i> and <i>RFC 2608</i>. SLP provides a scalable framework for the discovery and selection of network services.</p> <p><code>slpd</code> provides the following framework services:</p> <table><tr><td>Directory Agent</td><td>This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.</td></tr><tr><td>Service Agent Server</td><td>All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.</td></tr><tr><td>Passive Directory Agent Discovery</td><td>This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code>, obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.</td></tr><tr><td>Proxy Registration</td><td>This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.</td></tr></table> <p>All configuration options are available from the configuration file. <code>slpd</code> reads its configuration file upon startup.</p> <p>Stop and start the <code>slpd</code> daemon by using the startup script: <code>/etc/init.d/slpd</code>. Use the command <code>/etc/init.d/slpd stop</code> to stop the <code>slpd</code> daemon. Use the command <code>/etc/init.d/slpd start</code> to start it.</p> <p>The file <code>/etc/inet/slp.conf</code> must exist before the startup script can start the daemon. Only the example file <code>/etc/inet/slp.conf.example</code> is present by default. To enable SLP, copy <code>/etc/inet/slp.conf.example</code> to <code>/etc/inet/slp.conf</code>.</p>	Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.	Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.	Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.	Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.
Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.								
Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.								
Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.								
Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.								

OPTIONS The following options are supported:

`-f configuration-file` Specify an alternate configuration file

EXAMPLES **EXAMPLE 1** Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# /etc/init.d/slpd stop
```

EXAMPLE 2 Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# /etc/init.d/slpd start
```

FILES `/etc/inet/slp.conf` The default configuration file

`slpd.reg` The proxy registration file

smartcard(1M)

NAME	smartcard – configure and administer a smartcard
SYNOPSIS	<pre>smartcard -c admin [-a application] [propertyname...] smartcard -c admin [-a application] [-x { add delete modify} propertyname=value...] smartcard -c admin -t service -j classname -x { add delete modify} smartcard -c admin -t terminal -j classname -d device -r userfriendlyreadername -n readername -x { add delete modify} [-R] smartcard -c admin -t debug -j classname -l level -x { add delete modify} smartcard -c admin -t override -x { add delete modify} propertyname=value smartcard -c admin -I -k keytype -i filename smartcard -c admin -E -k keytype -o filename smartcard -c load -A aid [-r userfriendlyreadername] -P pin [-s slot] [-i inputfile] [-p propfile] [-v] [propertyname=value...] smartcard -c load -u -P pin [-A aid] [-r userfriendlyreadername] [-s slot] [-v] smartcard -c bin2capx -T cardname [-i inputfile] [-o outputfile] [-p propfile] [-I anothercapxfile] [-v] [propertyname=value...] smartcard -c init -A aid [-r readername] [-s slot] -L smartcard -c init -A aid [-r readername] -P pin [-s slot] [propertyname=value...] smartcard -c enable smartcard -c disable</pre>
DESCRIPTION	<p>The smartcard utility is used for all configurations related to a smartcard. It comprises various subcommands described below:</p> <ol style="list-style-type: none">1. Administration of OCF properties. (-c admin) This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properties are: <pre>defaultcard # default card for an application defaultreader # default reader for an application authmechanism # authentication mechanism to validcards # list of cards valid for an application</pre>A complete listing can be obtained by using the smartcard command as described in the EXAMPLES

section below.

2. Loading and Unloading of applets from the smartcard (-c load) and performing initial configuration of a non-Java card.

This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smartcard. The applet is a Java class file that has been run through a convertor to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the capx format. If no -r option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the smartcard -c admin command.

3. Converting card applets or properties to the capx format (-c bin2capx)

This subcommand is used to convert a Java card applet or properties into a new format called capx before downloading it onto the smartcard. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

In the following example,

```
smartcard -c bin2capx -i cyberflex.bin \
-T CyberFlex aidto-000102030405060708090A0B0C0D0E0F fileID=2222 \
instanceID=2223 and more.if no output file is specified, a default file with the name
input_filename.capx is created in the current directory. The mandatory -T option
requires the user to specify the card name for which the capx file is being
generated. The following example
```

```
smartcard -c bin2capx -T IButtontells the loader eventually that the capx file
contains the binary for IButton. A single capx file can hold binaries for multiple
cards (1 per card.) Users can, for example, hold binary files for both CyberFlex and
IButton in the same capx file as follows:
```

```
smartcard -c bin2capx -T IButton -i IButton.jib -o file.capxIn the following
example,
```

```
smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \
-l file.capx -o file.capxthe -l option is used to provide an already-generated
capx file. The output is directed to the same capx file, resulting in capx file
holding binaries for both cards.
```

4. Personalizing the smartcard (-c init)

This subcommand is used to set user-specific information required by an applet on a smartcard. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cards.

5. Enabling and disabling the host for smartcard (-c {enable | disable})

OPTIONS The following options are supported:

<i>-a application</i>	Specify application name for the configuration parameter. Parameters may differ depending on the
-----------------------	--

smartcard(1M)

	application. If no application name is specified, then <code>ocf</code> is the default application.
<code>-A aid</code>	Specify a unique alphanumeric string that identifies the applet. The <i>aid</i> argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical <i>aid</i> already exists on the card, a load will result in an error.
<code>-c</code>	Specify subcommand name. Valid options are: <code>admin</code> , <code>load</code> , <code>bin2capx</code> , <code>init</code> , <code>enable</code> and <code>disable</code> .
<code>-d device</code>	Specify device on which the reader is connected (for example, <code>/dev/cua/a</code>).
<code>-D</code>	Disable a system from using smartcards.
<code>-E</code>	Export the keys to a file.
<code>-i filename</code>	Specify input file name.
<code>-I</code>	Import from a file.
<code>-j classname</code>	Specify fully-qualified class name.
<code>-k keytype</code>	Specify type of key (for example, <code>challenge_response</code> , <code>pki</code> .)
<code>-l</code>	Specify debug level (0–9), signifying level of debug information displayed.
<code>-L</code>	List all properties configurable in an applet.
<code>-n readername</code>	Specify reader name as required by the driver.
<code>-o filename</code>	Specify output file name.
<code>-p propfile</code>	Specify properties file name. This file could contain a list of property names and value pairs, in the format <i>propertyname=value</i> .
<code>-P pin</code>	Specify pin used to validate to the card.
<code>-r userfriendlyreadername</code>	Specify user-defined reader name where the card to be initialized is inserted.
<code>-R</code>	Restart the <code>ocf</code> server.
<code>-s slot</code>	Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.
<code>-t</code>	Specify type of property being updated. The valid values are:

	<code>service</code>	Updating a card service provider details.
	<code>terminal</code>	Updating a card reader provider details.
	<code>debug</code>	OCF trace level.
	<code>override</code>	Override a system property of the same name.
<code>-T cardname</code>		Specify card name.
<code>-u</code>		Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.
<code>-v</code>		Verbose mode (displays helpful messages).
<code>-x</code>		Specify action to be taken. Valid values are: <code>add</code> , <code>delete</code> , or <code>modify</code> .

EXAMPLES**EXAMPLE 1** Viewing the Values of All Properties

Enter the following command to view the values of all the properties that are set:

```
% smartcard -c admin
```

EXAMPLE 2 Viewing the Values of Specific Properties

Enter the following command to view the values of specific properties:

```
% smartcard -c admin language country
```

EXAMPLE 3 Adding a Card Service

Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

```
% smartcard -c admin -t service \
-j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

EXAMPLE 4 Adding a Reader

Enter the following command to add a SCM reader, available in the package `com.sun.services.scm`, to the properties on device `/dev/cua/a` and assign it a name of SCM:

```
% smartcard -c admin -t terminal \
-j com.sun.opencard.terminal.scm.SCMStc.SCMstcCardTerminalFactory \
-x add -d /dev/cua/a -r SCM -n SunSCRI
```

smartcard(1M)

EXAMPLE 5 Deleting a Reader

Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```
% smartcard -c admin -t terminal -r SCM -x delete
```

EXAMPLE 6 Changing the Debug Level

Enter the following command to change the debug level for all of the com.sun package to 9:

```
% smartcard -c admin -t debug -j com.sun -l 9 -x modify
```

EXAMPLE 7 Setting the Default Card for an Application

Enter one of the following commands to set the default card for an application (dtlogin) to be CyberFlex.

If the property default card does not exist, enter the following command:

```
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:

```
% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex
```

EXAMPLE 8 Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

```
% smartcard -c admin -k challenge_response -E -o /tmp/mykeys
```

EXAMPLE 9 Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

```
% smartcard -c admin -k challenge_response -I -i /tmp/mykeys
```

EXAMPLE 10 Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into a SCM reader for the capx file supplied in the /usr/share/lib/smartcard directory:

```
% smartcard -c load -r SCM \  
-i /usr/share/lib/smartcard/SolarisAuthApplet.capx
```

EXAMPLE 11 Downloading an Applet Binary

Enter the following command to download an applet binary from some place other than the capx file supplied with Solaris8 into an IButton (the AID and input file are mandatory, the remaining parameters are optional):

```
% smartcard -c load -A A000000062030400 -i newapplet.jib
```

EXAMPLE 12 Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

```
% smartcard -c load -A newAID -i newapplet.bin \
fileID=2222 instanceID=3333 verifyKey=newKey \
MAC=newMAC heapsize=2000
```

EXAMPLE 13 Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific AID, transport key, and initial pin:

```
% smartcard -c load aid-A00000006203400 \
pin=242424246A617661 transportKey=4746584932567840
```

EXAMPLE 14 Unloading an Applet from a Card

Enter the following command to unload an applet from iButton:

```
% smartcard -c load -u
```

EXAMPLE 15 Displaying Usage of smartcard -c load

Enter the following command to display the usage of the smartcard -c load command:

```
% smartcard -c load
```

EXAMPLE 16 Displaying All Configurable Parameters for an Applet

Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SM reader:

```
% smartcard -c init -r SM -A 123456 -L
```

EXAMPLE 17 Changing the Pin

Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the pin for a PayFlex (non-Java) card inserted into an SM reader:

smartcard(1M)

EXAMPLE 17 Changing the Pin (Continued)

```
% smartcard -c init -A A000000062030400 -P oldpin pin=newpin
```

EXAMPLE 18 Displaying All Configurable Parameters for the SolarisAuthApplet.

Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SM reader:

```
% smartcard -c init -A A000000062030400 -L
```

EXAMPLE 19 Setting a Property to a Value on a Smartcard

Enter the following command to set properties called "user" to the value "james" and "application" to the value "login" on a card inserted into an SM reader that has a pin "testpin":

```
% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \  
application=login user=james
```

EXAMPLE 20 Converting an Applet for the CyberFlex Card into capx Format.

Enter the following command to convert an applet for the CyberFlex card into the capx format required for downloading the applet into the card:

```
% smartcard -c bin2capx \  
-i /usr/share/lib/smartcard/SolarisAuthApplet.bin \  
-T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12
```

EXAMPLE 21 Converting an Applet for the IButton Card into capx Format

Enter the following command to convert an applet for the IButton card into the capx format required for downloading the applet into the button:

```
% smartcard -c bin2capx -i /usr/share/lib/smartcard/SolarisAuthApplet.jib \  
-T IButton -o /home/CorporateCard.capx -v
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
1 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES The command line options contain only alphanumeric input.

smattrpop(1M)

NAME	smattrpop – populate security attribute databases in a name service
SYNOPSIS	smattrpop [-c] [-f] [-m] [-p <i>policy</i>] [-r] -s <i>scope</i> -t <i>scope</i> [-v] <i>database</i>
DESCRIPTION	<p>The <code>smattrpop</code> command updates the <code>auth-attr(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> role-based access control databases in a target NIS, NIS+, LDAP, or local <code>/etc</code> files name service from the corresponding databases in a source name service or files.</p> <p>This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.</p> <p>Any errors encountered while updating the target entry are reported to <code>stdout</code>, and the command continues with the next source database entry.</p>
OPTIONS	<p>The following options are supported:</p> <p>-c Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to <code>stdout</code>.</p> <p> The target entry values are checked against entries in related databases:</p> <ul style="list-style-type: none">■ <code>auths</code> values — Each value must exist as the name of an authorization in the <code>auth-attr(4)</code> database.■ <code>profiles</code> values — Each value must exist as a name of a profile in the <code>prof_attr(4)</code> database.■ <code>roles</code> values — Each value must exist as the name of a role identity in the <code>user_attr(4)</code> database.■ For each <code>exec_attr(4)</code> entry in the source database, the name must exist as the name of a <code>profile</code> in the <code>prof_attr(4)</code> database. <p>-f Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.</p> <p>-m For the <code>auths</code>, <code>profiles</code>, and <code>roles</code> attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:</p> <ul style="list-style-type: none">■ <code>prof_attr(4)</code> — the <code>auths</code> and <code>profiles</code> attribute values are merged.

	<ul style="list-style-type: none"> ■ <code>user_attr(4)</code> — the <code>auths</code>, <code>profiles</code>, and <code>roles</code> attribute values are merged. ■ <code>exec_attr(4)</code> — the <code>uid</code>, <code>gid</code>, <code>euid</code>, and <code>egid</code> values are merged.
<code>-p policy</code>	Specifies the value of the <code>policy</code> field in the <code>exec_attr(4)</code> database. Valid values are <code>suser</code> (standard Solaris superuser) and <code>tsol</code> (Trusted Solaris). If you specify this option, only the entries in the source <code>exec_attr</code> database with the specified policy are processed. If you omit this option, all entries in the source <code>exec_attr</code> database are processed.
<code>-r</code>	Specifies that role identities in the <code>user_attr(4)</code> database in the source name service are processed. If you omit this option, only the normal user entries in the <code>user_attr</code> source database are processed.
<code>-s scope</code>	<p>Specifies the source name service or local file directory for database updates, using the following syntax:</p> <p><i>type</i>: <i>/server/domain</i></p> <p>where <i>type</i> indicates the type of name service. Valid values for <i>type</i> are:</p> <ul style="list-style-type: none"> ■ <code>file</code> — local files ■ <code>nis</code> — NIS name service ■ <code>nisplus</code> — NIS+ name service ■ <code>ldap</code> — LDAP name service <p><i>server</i> indicates the local host name of the Solaris system on which the <code>smattrpop</code> command is executed, and on which both the source and target databases exist.</p> <p><i>domain</i> specifies the management domain name for the name service.</p> <p>You can use two special cases of <i>scope</i> values:</p> <ul style="list-style-type: none"> ■ To indicate the databases in the <code>/etc/security</code> local system directory, use the scope <code>file:/server</code>, where <i>server</i> is the name of the local system. ■ To load from databases in an arbitrary directory on the Solaris server, use the scope <code>file:/server/pathname</code>, where <i>server</i> is the name of the local system and <i>pathname</i> is the fully-qualified directory path name to the database files.
<code>-t scope</code>	<p>Specifies the target name service or local file directory for database updates, using the following syntax:</p> <p><i>type</i>: <i>/server/domain</i></p>

smattrpop(1M)

where *type* indicates the type of name service. Valid values for *type* are:

- *file* — local files
- *nis* — NIS name service
- *nisplus* — NIS+ name service
- *ldap* — LDAP name service

server indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file:/server`, where *server* is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope `file:/server/pathname`, where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

`-v` Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

OPERANDS The following operands are supported:

database Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:

1. `auth_attr(4)`
2. `prof_attr(4)`
3. `exec_attr(4)`
4. `user_attr(4)`

EXAMPLES **EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.sun.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

EXAMPLE 1 Populating all tables in the NIS name service (Continued)

```
/usr/sadm/bin/smattrpop -s file:/hoosier \  
-t nis:/hoosier/east.sun.com all
```

EXAMPLE 2 Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the `auth_attr` text format into the existing `auth_attr` database in the NIS+ domain, `east.sun.com`. The command is executed on the NIS+ master server, `foobar`. Values from the source `auth_attr` file replace the corresponding field values in the NIS+ tables for each entry. A message is written to `stdout` for each entry processed. Database cross-checking is performed and any check error is written to `stdout`. A summary message indicating the number of entries processed and updated for the `auth_attr` database is written to `stdout`.

```
/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \  
-t nisplus:/foobar/East.Sun.COM auth_attr
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smattrpop` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

Any errors encountered while updating the target entry are reported to `stdout`. The following exit values are returned:

- 0 The specified tables were updated. Individual entries may have encountered checking errors.
- 1 A syntax error occurred in the command line.
- 2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

FILES

<code>/etc/security/auth_attr</code>	Authorization description database. See <code>auth_attr(4)</code> .
<code>/etc/security/exec_attr</code>	Execution profiles database. See <code>exec_attr(4)</code> .
<code>/etc/security/prof_attr</code>	Profile description database. See <code>prof_attr(4)</code> .
<code>/etc/user_attr</code>	Extended user attribute database. See <code>user_attr(4)</code> .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

smattrpop(1M)

NAME	smc – start the Solaris Management Console
SYNOPSIS	<pre>smc [subcommand] [args] smc [subcommand] [args] -T tool_name [- - tool_args]</pre>
DESCRIPTION	<p>The <code>smc</code> command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server.</p> <p>The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it.</p> <p>The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script.</p> <p>For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the "Help" menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the <code>smc edit</code> command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select "Contents," then "About the Solaris Management Console Editor," then "To Create a Toolbox."</p>
<i>subcommands</i>	<p><code>smc subcommands</code> are:</p> <p><code>open</code> The default subcommand for the Solaris Management Console is <code>open</code>. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line.</p> <p><code>edit</code> The <code>edit</code> subcommand will also launch the console, like the <code>open</code> subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.</p>
OPTIONS	<p>The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code> with the <i>domain</i> argument.</p> <p>If <i>tool_args</i> are specified, they must be preceded by the <code>--</code> option and separated from the double dashes by a space.</p>

smc(1M)

- `-auth-data file`
Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the `-u`, `-p`, `-r`, and `-l` options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of *file* is:

hostname=*host name*
username=*user name*
password=*password for user name*
rolename=*role name*
rolepassword=*password for role name*

Only one set of *hostname-username-password-rolename-rolepassword* may be specified in any one file. If the *rolename* is not specified, no role will be assumed.
- B | - `-toolbox toolbox`
Loads the specified toolbox. *toolbox* can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,

`http://host_name:port/ . . .`

it must point to a *host_name* and *port* on which an Solaris Management Console server is running. If you omit *port*, the default port, 898, is used. This option overrides the `-H` option.
- D | - `-domain domain`
Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is *nis*, *nisplus*, *dns*, *ldap*, or *file*; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*) This option applies only to a single tool run in the terminal console.

If you do not specify this option, the Solaris Management Console assumes the *file* default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
- h | - `-help`
Prints a usage statement about the `smc` command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter `-h` after the subcommand.
- H | - `-hostname host_name:port`
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify

host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `-B` option (see above), or set your console preferences to load a “home toolbox” by default.

`-J`*java_option*

Specifies an option that can be passed directly to the Java runtime (see `java(1)`). Do not enter a space between `-J` and the argument. This option is most useful for developers.

`-l` | `-`*rolepassword* *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `-`*password* *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `-`*rolename* *role_name*

Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.

`-s` | `-`*silent*

Disables informational messages printed to the terminal.

`-t`

Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.

`-`*trust*

Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

`-T` | `-`*tool* *tool_name*

Runs the tool with the Java class name that corresponds to *tool_name*. If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options `-H` and `-B`).

`-u` | `-`*username* *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

smc(1M)

-v | **-** *-version*

Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the About box, available from the Help menu.

-y | **-** *-yes*

Answers *yes* to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

EXAMPLES **EXAMPLE 1** Printing a Usage Statement

The following prints a usage statement about the `smc` command to the terminal window:

```
smc --help
```

EXAMPLE 2 Passing an Option to Java

The following passes an option through to the Java VM, which sets the `com.example.boolean` system property to `true`. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the following environment variable that affects the execution of the `smc` command:

`JAVA_HOME` If you do not specify this environment variable, the `/usr/java1.2` location is used.

EXIT STATUS

The following exit values are returned. Other error codes may be returned if you specify a tool (using `-T tool_name`) that has its own error codes. See the documentation for the appropriate tool.

0 Successful completion.

1 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME	smcconf – configure the Solaris Management Console
SYNOPSIS	<pre> /usr/sadm/bin/smcconf [-h] [-v] toolbox [action] [target] [parameters] [options] /usr/sadm/bin/smcconf [-h] [-v] repository [action] [target] [parameters] [options] </pre>
DESCRIPTION	<p>The <code>smcconf</code> command configures the Solaris Management Console. See <code>smc(1M)</code>. This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository.</p> <p>Using <code>smcconf</code> to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, <code>smc edit</code>. See <code>smc(1M)</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -h Prints out a usage summary for the command. -v Verbose option. Displays the debugging output at any time.
Toolbox Configuration	<p><i>action</i> Legal values are:</p> <ul style="list-style-type: none"> add <ul style="list-style-type: none"> Adds a <i>target</i> to the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option. remove <ul style="list-style-type: none"> Removes a <i>target</i> from the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option. create <ul style="list-style-type: none"> Creates a new toolbox with no tools in it. The only <i>target</i> recognized is <code>toolbox</code>. list <ul style="list-style-type: none"> Lists the contents of the toolbox. No <i>target</i> is recognized. If you specify a <i>parameter</i>, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a <i>parameter</i>, the contents of the default toolbox are listed. <p><i>target</i> Legal values are:</p> <ul style="list-style-type: none"> tool <ul style="list-style-type: none"> If the <i>action</i> is specified as <code>add</code>, this target adds a native Solaris Management Console tool from the toolbox. The required <i>parameter</i> is the full Java classname of the tool you are adding. If

you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.

If the *action* is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you wish to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed.

For the tool to show up in the console, the tool must also be registered in the repository. See the `repository configuration` section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.

Removing a tool from a toolbox does not remove the tool from the server repository.

`tbxURL`

If the *action* is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required *parameter* is the URL to the other toolbox.

The properties of addition and removal are the same as for the `tool target`.

`toolbox`

If the *action* is specified as `create`, this target creates a skeleton toolbox with no tools. There are four required *parameters*: the toolbox name, description, and small and large icon paths. These must be followed by the `-B toolboxpath` and `-D scope` options.

`legacy`

If the *action* is specified as `add` or `remove`, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required, and the `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See NOTES for more information about legacy applications.

`folder`

If the *action* is specified as `add`, this target adds a folder to the toolbox. There are four required *parameters*: the folder name, description, and small and large icon paths.

If the *action* is specified as *remove*, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the *-F* option.

parameters

Specifies values that may be required depending on the combination of *action* and *target*.

options

Supported options for various *action* and *target* combinations for the `toolbox` configuration are:

-A *parameters*

Specifies the parameters to pass to the legacy application. This option is available only for the *legacy* target.

-B *toolboxpath*

Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "This Computer".

-D *scope*

Specifies the scope (domain) in which the tool should be run. The legal values for *scope* are *file*, *nis*, *nisplus*, *dns*, and *ldap*. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.

-E *appPath*

Specifies the absolute executable path of the legacy application. This option is available only for the *legacy* target.

-F *folder*

Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox.

-H [*host_name*][:*port*]

Specifies the host and port from which a tool should be loaded. If *host_name* is not given, the default host (`localhost`, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If *:port* is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.

-L *locale*

Specifies the locale of the toolbox which is being modified. The default is the C locale.

Repository Configuration

-N *appName*
Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the legacy target.

-P *key:value*
Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

-T *appType*
Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the legacy target.

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

action Legal values are:

add
Adds information to the repository. If the -f option is given to add, the information will overwrite any information of the same name already in the repository. If the -f option is not given, an error may be returned if the information is already in the repository.

remove
Removes information from the repository.

list
Lists the contents of the repository:

- all registered tools
- all registered services
- all libraries attached to all tools
- all libraries attached to all services
- all libraries attached to all tools and services

target Legal values are:

bean
If the *action* is specified as add, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required *parameter* is the path to the jar file that contains the bean to be added.

If the *action* is specified as remove, this target will remove a tool or service bean from the repository. The required *parameter* is the full Java classname of the desired bean.

library

If the *action* is specified as `add`, this target adds a “library” jar file to a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the “pseudo-beans”, `ALL`, `ALLTOOL`, or `ALLSERVICE`, in which case the library will be attached, respectively, to all beans, all tools, or all services in the repository.

If the *action* is specified as `remove`, this target detaches a “library” jar file from a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the name of the jar file that is attached. As with the `add` action, the three “pseudo-beans” `ALL`, `ALLTOOL`, or `ALLSERVICE` can be used.

property

If the *action* is specified as `add`, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,

```
-P key=value
```

Following this property list is a “pseudo-bean name”, *pseudoBeanName*, as defined for the `library` target, on which the properties will be defined. Optionally, a library name may follow the “pseudo-bean” name, in which case the properties are defined on the library that is attached to the named bean.

If the *action* is specified as `remove`, this target undefines a property on a tool or service. The key/value pairs, “pseudo-bean” name, and optional library are specified as for the `add` action.

EXAMPLES **EXAMPLE 1** Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the Command Line Interface (CLI) application, `/usr/bin/ls` with arguments `-al -R`, giving it the name, Directory Listing:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard “Management Tools” toolbox a folder with the name, `New Folder`, the description, `This is a new folder`, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

```
/usr/sadm/bin/smcconf toolbox add folder "New Folder" \
"This is a new folder" folder_s.gif folder_l.gif \
```

EXAMPLE 2 Adding a Folder to a Toolbox (Continued)

```
-B /var/sadm/smc/toolboxes/smc/smc.tbx
```

EXAMPLE 3 Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `HelloWorld.client>HelloTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, `syrix`, which is hosted by the machine, `temple`, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
/usr/sadm/bin/smcconf toolbox add tool HelloWorld.client>HelloTool \  
-D nis:/temple/syrix -H :2112
```

EXAMPLE 4 Adding a Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `HelloWorld.jar` to the repository. The jar file contains information that the bean is a tool.

```
/usr/sadm/bin/smcconf repository add bean HelloWorld.jar
```

EXAMPLE 5 Removing a Solaris Management Console Service from the Repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely convention; the repository knows whether a particular registered bean is a tool or a service.

```
/usr/sadm/bin/smcconf repository remove bean \  
HelloWorld.server>HelloService
```

EXAMPLE 6 Attaching a Library to a Tool

The following command adds the library jar file, `HelloWorld_fr.jar` (probably a French localized version of the `HelloTool`'s resources) to the bean, `HelloWorld.client>HelloTool`:

```
/usr/sadm/bin/smcconf repository add library \  
HelloWorld.client>HelloTool HelloWorld_fr.jar
```

EXAMPLE 7 Attaching a Library to all Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools.

```
/usr/sadm/bin/smcconf repository add library ALLTOOL widgets.jar
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of the `smcconf` command:

<code>JAVA_HOME</code>	If you do not specify this environment variable, the <code>/usr/java1.2</code> location is used.
<code>DISPLAY</code>	If you do not set this environment variable, set it to null, or set it to an X(7) display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmc

SEE ALSO

`jar(1)`, `java(1)`, `javac(1)`, `smc(1M)`, `attributes(5)`, `environ(5)`

NOTES

All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from “native” Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, `LegacyAppLauncher`, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

smcron(1M)

NAME	smcron – manage jobs in the crontab database								
SYNOPSIS	<code>/usr/sadm/bin/smcron subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The smcron command manages jobs in the crontab(1) database.								
<i>subcommands</i>	<p>smcron <i>subcommands</i> are:</p> <table><tr><td>add</td><td>Adds a job to the crontab(1) database. To add a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To add a job to another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.</td></tr><tr><td>delete</td><td>Deletes a job from the crontab(1) database. To delete a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To delete a job from another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.</td></tr><tr><td>list</td><td>Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the <code>solaris.jobs.user</code> authorization. To list a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization. No authorization is needed to list a user's own jobs.</td></tr><tr><td>modify</td><td>Modifies a job in the crontab(1) database. To modify a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To modify a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.</td></tr></table>	add	Adds a job to the crontab(1) database. To add a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To add a job to another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.	delete	Deletes a job from the crontab(1) database. To delete a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To delete a job from another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.	list	Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the <code>solaris.jobs.user</code> authorization. To list a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization. No authorization is needed to list a user's own jobs.	modify	Modifies a job in the crontab(1) database. To modify a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To modify a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.
add	Adds a job to the crontab(1) database. To add a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To add a job to another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.								
delete	Deletes a job from the crontab(1) database. To delete a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To delete a job from another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.								
list	Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the <code>solaris.jobs.user</code> authorization. To list a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization. No authorization is needed to list a user's own jobs.								
modify	Modifies a job in the crontab(1) database. To modify a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To modify a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.								
OPTIONS	<p>The smcron authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smcron command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>								
<i>auth_args</i>	<p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p>-D - -domain <i>domain</i> Specifies the default domain that you want to manage. smcron accepts only file for this option. file is also the default value.</p>								

The `file` default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - --hostname host_name:port`

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smcron(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l | - --rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - --password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - --rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - --username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- -`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

- `-c command` Specifies the command that you want to run.
- `-h` (Optional) Displays the command's usage statement.
- `-m day_of_month` (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.

smcron(1M)

- M *month* (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both -t and -M options, the job executes during the specified month at the time specified by -t.
 - n *name* Specifies the unique name of the job.
 - o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.
 - t *time_of_day* Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (-m, -M, or -w), the job executes every day at the time specified by -t. If you specify both -t and -w options, the job executes one day per week at the time specified by -t. If you specify both -t and -m options, the job executes one day per month at the time specified by -t. If you specify both -t and -M options, the job executes each day during the specified month at the time specified by -t.
 - w *day_of_week* (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
 - 0=Sunday
 - 1=Monday
 - 2=Tuesday
 - 3=Wednesday
 - 4=Thursday
 - 5=Friday
 - 6=SaturdayIf you specify both -t and -w options, the job executes one day per week at the time specified by -t.
- For subcommand `delete`:
 - h (Optional) Displays the command's usage statement.
 - n *name* Specifies the unique name of the job.
 - o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.
 - For subcommand `list`:
 - f *n|s|v* (Optional) Specifies the format of the output. See EXAMPLES for examples of each output type.
 - *n* — Displays the data in native format, as it appears in the `crontab(1)` database.
 - *s* — Default format. Displays the data in summary format.
 - *v* — Displays the data in verbose format.

- h (Optional) Displays the command's usage statement.
- o *owner* (Optional) Lists all jobs for the specified owner (user name). If you do not specify this option, all jobs in the `crontab(1)` database are listed.

■ For subcommand `modify`:

- c *command* (Optional) Specifies the command that you want to run.
- h (Optional) Displays the command's usage statement.
- m *day_of_month* (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.
- M *month* (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both `-t` and `-M` options, the job executes during the specified month at the time specified by `-t`.
- n *name* Specifies the current unique name of the job.
- N *new_name* (Optional) Specifies the new unique name of the job.
- o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.
- O *new_owner* (Optional) Specifies the new owner of the job.
- t *time_of_day* (Optional) Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (`-m`, `-M`, or `-w`), then the job executes every day at the time specified by `-t`. If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`. If you specify both `-t` and `-M`, then the job executes each day during the specified month at the time specified by `-t`.
- w *day_of_week* (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
 - 0=Sunday
 - 1=Monday
 - 2=Tuesday
 - 3=Wednesday
 - 4=Thursday
 - 5=Friday
 - 6=Saturday

If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`.

smcron(1M)

EXAMPLES

EXAMPLE 1 Adding a job

The following adds a new job, owned by root, that removes the old log files from /tmp daily at 1:30 AM.

```
./smcron add -H myhost -u root -p mypassword -- -n "Remove old logs" \  
-t 1:30 -c "rm /tmp/*.log" -o root
```

EXAMPLE 2 Deleting a job

The following deletes the job Remove old logs owned by root:

```
./smcron delete -H myhost -u root -p mypassword -- \  
-n "Remove old logs" -o root
```

EXAMPLE 3 Listing jobs in native format

The following lists all jobs in native, or crontab(1), format:

```
./smcron list -H myhost -u root -p mypassword -- -f n  
MINUTE HOUR DATE MONTH DAY COMMAND  
  
10 3 * * 0,4 /etc/cron.d/logchecker  
10 3 * * 0 /usr/lib/newsyslog  
15 3 * * 0 /usr/lib/fs/nfs/nfsfind  
1 2 * * * [ -x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1
```

EXAMPLE 4 Listing jobs in standard format

The following lists all jobs owned by lp in standard format:

```
./smcron list -H myhost -u root -p mypassword -- -f s -o lp  
NAME::OWNER::SCHEDULE::COMMAND  
  
NoName_1765663371::lp::Weekly on Sundays at 3:13 AM::cd /var/lp/logs;  
if [ -f requests ]; then if [ -f requests.1 ]; then /bin/mv requests.1  
requests.2; fi; /usr/bin/cp requests requests.1; > requests; fi  
NoName_512822673::lp::Weekly on Sundays at 4:15 AM::cd /var/lp/logs;  
if [ -f lpsched ]; then if [ -f lpsched.1 ]; then /bin/mv lpsched.1  
lpsched.2; fi; /usr/bin/cp lpsched lpsched.1; >lpsched; fi
```

EXAMPLE 5 Listing jobs in verbose format

The following lists all jobs in verbose format:

```
./smcron list -H myhost -u root -p mypassword -- -f v  
NAME::OWNER::SCHEDULE::NEXT_RUN::STATUS::COMMAND  
  
NoName_1075488942::root::Advanced:::Finished on Feb 10 3:10 with code 1  
::/etc/cron.d/logchecker  
databackup::root::Weekly on Sundays at 3:10 AM::3/19/00 3:10 AM  
::Finished on Sep 19 3:10::/usr/lib/newsyslog  
runlog::root::Daily at 2:01 AM::3/14/00 2:01 AM::Finished on Feb 11
```

EXAMPLE 5 Listing jobs in verbose format (Continued)

```
2:01 AM:./usr/sbin/rtc
```

EXAMPLE 6 Changing a job

The following modifies the job Remove old logs owned by root to execute daily at 2:00 AM:

```
./smcron modify -H myhost -u root -p mypassword -- -n "Remove old logs" \  
-o root -t 2:00
```

**ENVIRONMENT
VARIABLES**

See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smcron` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

<code>auth_args</code>	<p>The valid <code>auth_args</code> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <code>auth_args</code> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>- -domain</code>.</p> <p>Note – <code>smdiskless</code> supports the <code>--auth-data file</code> option, which enables you to specify a file the console can read to collect authentication data. See <code>smc(1M)</code> for a description of this option.</p> <p><code>-D - -domain domain</code></p> <p>Specifies the default domain that you want to manage. The syntax of <code>domain</code> is <code>type:/host_name/domain_name</code>, where <code>type</code> is <code>nis</code>, <code>nis+</code>, <code>dns</code>, <code>ldap</code>, or <code>file</code>; <code>host_name</code> is the name of the machine that serves the domain; and <code>domain_name</code> is the name of the domain you want to manage. (Note: Do not use <code>nis+</code> for <code>nisplus</code>.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the <code>file</code> default domain on whatever server you choose to manage, meaning that</p>								

changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | **-** *-hostname host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a “home toolbox” by default.

-l | **-** *-rolepassword role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | **-** *-password password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | **-** *-rolename role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | **-** *-username user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

- h** (Optional) Displays the command’s usage statement.
- i** *IP_address* Specifies the IP address for the host in the form of 129.9.200.1.
- e** *ethernet_addr* Specifies the Ethernet address.
- n** *host* Specifies the client name.
- o** *os_server* (optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in

smdiskless(1M)

	the event that the name service server and the OS server are not the same machine.
<code>-x platform=<i>platform</i></code>	<p>Specifies the operating system. The syntax for <i>platform</i> is as follows:</p> <p><i>instruction_set.implementation.Solaris_version</i></p> <p>where</p> <ul style="list-style-type: none">■ <i>instruction_set</i> is one of <code>sparc</code> or <code>i386</code>■ <i>implementation</i> is the implementation architecture, that is, <code>i86pc</code>, <code>sun4c</code> (for Solaris 2.6 and 7 only), <code>sun4d</code>, <code>sun4m</code>, and <code>sun4u</code>.■ <i>version</i> is the Solaris version number. The supported <i>version</i> numbers are 2.6, 2.7 (for Solaris 7), and 8 (for Solaris 8). Examples are: <p><code>sparc.sun4c.Solaris_2.7</code> <code>sparc.sun4d.Solaris_8</code></p>
<code>-x root=<i>pathname</i></code>	(Optional) Specifies the absolute path of the directory in which to create the root directory for diskless clients. The default (and recommended) <i>pathname</i> is <code>/export/root/client_name</code> .
<code>-x swap=<i>pathname</i></code>	(Optional) Specifies the absolute path of the directory in which to create the swap file for diskless clients. The default (and recommended) <i>pathname</i> is <code>/export/swap/client_name</code> .
<code>-x swapsize=<i>size</i></code>	(Optional) Specifies the size, in megabytes, of the swap file for diskless clients. The default swap size is 24M.
<code>-x dump=<i>pathname</i></code>	(Optional) Specifies the absolute path of the dump directory for diskless clients. The default (and recommended) <i>pathname</i> is <code>/export/dump/client_name</code> .
<code>-x dumpsize=<i>size</i></code>	(Optional) Specifies the size, in megabytes, of the dump file for diskless clients. The default swap size is 24M.
<code>-x pw=Y</code>	(Optional) Prompts for the system's root password. The default is not to prompt. The following options are used to configure workstations on first boot by <code>sysidtool(1M)</code> . They can either be specified on the command line, or in a <code>sysidcfg(4)</code> formatted file. <i>Note:</i> Use the <code>sysidcfg(4)</code> file to:

- Add a DNS client.
- Specify use of the LDAP name service.
- Specify a security policy.

The keywords and functions supported by `sysidtool` and `sysidcfg` vary among Solaris releases. Consult the man pages for your operating system release (`uname -r`) to determine the level of support available.

`-x tz=timezone`

(Optional) Specifies the path of a timezone file, relative to `/usr/share/lib/zoneinfo`. The default is the server's timezone.

`-x ns=NIS | NIS+ | NONE`

(Optional) Specifies the client's nameservice. This is one of NIS, NIS+, or NONE. Use a `sysidcfg(4)` file to specify DNS or LDAP. The default `ns` value is NONE, which results in the use of the `files` source in `nsswitch.conf`. See `nsswitch.conf(4)` for a description of the `files` source.

`-x nameserver=hostname`

(Optional) Specifies the nameserver's hostname. The default is the server's nameserver.

`-x domain=domain`

(Optional) Specifies the client's domain. The default is the server's domain.

`-x nameserver_ipaddress=ip_address`

(Optional) Specifies the nameserver's IP address.

`-x netmask=ip_address`

(Optional) Specifies the client's IP address netmask. The default is the server's netmask.

`-x locale=locale`

(Optional) Specifies the client's system locale. The default is the C locale.

`-x terminal=term`

(Optional) Specifies the workstation's terminal type, typically, `sun` or `xterms`.

`-x passwd=root_password`

(Optional) Specifies the system's root password. The default is no password.

`-x sysidcfg=path_to_sysidcfg_file`

(Optional) Specifies the file to be placed in the `/etc` directory of the diskless client. On first boot, `/etc/.UNCONFIGURED` exists and `sysidtool(1M)` will run. If a file called `/etc/sysidcfg` exists, `sysidtool(1M)` reads this file and uses the information for system configuration.

- For subcommand `delete`:

`-h` (Optional) Displays the command's usage statement.

`-n host` Specifies the hostname of the diskless client to delete. This host is deleted from relevant tables and OS Services for this client are deleted.

smdiskless(1M)

`-o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `list`:

`-h` (Optional) Displays the command's usage statement.

`-o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `modify`:

`-e ethernet_addr` Changes the specified diskless client's ethernet address to `ethernet_addr`.

`-h` (Optional) Displays the command's usage statement.

`-n host` Specifies the host name of the diskless client to modify.

`-o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

`-x tz=timezone` (Optional) Changes the specified diskless client's timezone.

EXAMPLES

EXAMPLE 1 Creating a new diskless client

The following command adds a new diskless client named `client1` which will run Solaris 8 on a `sun4u` machine:

```
example% /usr/sadm/bin/smdiskless add -- -i 129.9.200.1 \  
-e 8:0:11:12:13:14 -n client1 -x os=sparc.sun4u.Solaris_8 \  
-x root=/export/root/client1 -x swap=/export/swap/client1 \  
-x swapsize=32 -x tz=US/Eastern -x locale=en_US
```

EXAMPLE 2 Deleting an existing diskless client

The following command deletes the diskless client named `client1` from the OS server named `osserver`, where the OS server is using NIS+ and the NIS+ server is `nisplusservice`:

```
example% /usr/sadm/bin/smdiskless delete \  
-D nisplus:/nisplusservice/my.domain.com -- \  
-o osserver -n client1
```

EXAMPLE 3 Listing the diskless clients served by a host

The following command lists the diskless clients running on the OS server, `osserver`:

```
example% /usr/sadm/bin/smdiskless list -D file:/osserver/osserver -- \
        -o oserver
```

EXAMPLE 4 Modifying the attributes of the diskless client host

The following command modifies the ethernet address for the client named `client1` on the OS server, `osserver`, to be `8:0:11:12:13:15`:

```
example% /usr/sadm/bin/smdiskless modify -D file:/osserver/osserver -- \
        -o oserver -n client1 -e 8:0:11:12:13:15
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smdiskless` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdclnt

smexec(1M)

NAME	smexec – manage entries in the exec_attr database
SYNOPSIS	<code>/usr/sadm/bin/smexec subcommand [auth_args] - - [subcommand_args]</code>
DESCRIPTION	The smexec command manages an entry in the exec_attr(4) database in the local /etc files name service or a NIS or NIS+ name service.
<i>subcommands</i>	<p>smexec subcommands are:</p> <p>add Adds a new entry to the exec_attr(4) database. To add an entry to the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</p> <p>delete Deletes an entry from the exec_attr(4) database. To delete an entry from the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</p> <p>modify Modifies an entry in the exec_attr(4) database. To modify an entry in the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</p>
OPTIONS	<p>The smexec authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smexec command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>
<i>auth_args</i>	<p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p>-D - -domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.</p> <p>-H - -hostname <i>host_name:port</i> Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i>, the system connects to the default port, 898. If you do not specify</p>

host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l` | `-` `-rolepassword` *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `-` `-password` *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `-` `-rolename` *role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `-` `-username` *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`-` `-`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `-` `-` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

- `-c` *command_path* Specifies the full path to the command associated with the new `exec_attr` entry.
- `-g` *egid* (Optional) Specifies the effective group ID that executes with the command.
- `-G` *gid* (Optional) Specifies the real group ID that executes with the command.
- `-h` (Optional) Displays the command's usage statement.
- `-n` *profile_name* Specifies the name of the profile associated with the new `exec_attr` entry.
- `-t` *type* Specifies the type for the command. Currently, the only acceptable value for *type* is `cmd`.
- `-u` *euid* (Optional) Specifies the effective user ID that executes with the command.

smexec(1M)

- U *uid* (Optional) Specifies the real user ID that executes with the command.
- For subcommand `delete`:
 - c *command_path* Specifies the full path to the command associated with the `exec_attr` entry.
 - h (Optional) Displays the command's usage statement.
 - n *profile_name* Specifies the name of the profile associated with the `exec_attr` entry.
 - t *type* Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
- For subcommand `modify`:
 - c *command_path* Specifies the full path to the command associated with the `exec_attr` entry that you want to modify.
 - g *egid* (Optional) Specifies the new effective group ID that executes with the command.
 - G *gid* (Optional) Specifies the new real group ID that executes with the command.
 - h (Optional) Displays the command's usage statement.
 - n *profile_name* Specifies the name of the profile associated with the `exec_attr` entry.
 - t *type* Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
 - u *euid* (Optional) Specifies the new effective user ID that executes with the command.
 - U *uid* (Optional) Specifies the new real user ID that executes with the command.

EXAMPLES

EXAMPLE 1 Creating an `exec_attr` database entry

The following creates a new `exec_attr` entry for the `User Manager` profile on the local file system. The entry type is `cmd` for the command `/usr/bin/cp`. The command has an effective user ID of 0 and an effective group ID of 0.

```
./smexec add -H myhost -p mypasswd -u root -- -n "User Manager" \  
-t cmd -c /usr/bin/cp -u 0 -g 0
```

EXAMPLE 2 Deleting an `exec_attr` database entry

The following example deletes an `exec_attr` database entry for the `User Manager` profile from the local file system. The entry designated for the command `/usr/bin/cp` is deleted.

EXAMPLE 2 Deleting an exec_attr database entry (Continued)

```
./smexec delete -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp
```

EXAMPLE 3 Modifying an exec_attr database Entry

The following modifies the attributes of the exec_attr database entry for the User Manager profile on the local file system. The /usr/bin/cp entry is modified to execute with the real user ID of 0 and the real group ID of 0.

```
./smexec modify -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp -U 0 -G 0
```

ENVIRONMENT VARIABLES

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smexec command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following file is used by the smexec command:

/etc/security/exec_attr Execution profiles database. See exec_attr(4).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO

smc(1M), exec_attr(4), attributes(5), environ(5)

smgroup(1M)

NAME	smgroup – manage group entries								
SYNOPSIS	<code>/usr/sadm/bin/smgroup subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	<p>The smgroup command manages one or more group definitions in the group database for the appropriate files in the local /etc files name service or a NIS or NIS+ name service.</p>								
<i>subcommands</i>	<p>smgroup <i>subcommands</i> are:</p> <table><tr><td>add</td><td>Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr><tr><td>delete</td><td>Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.</td></tr><tr><td>list</td><td>Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr><tr><td>modify</td><td>Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr></table>	add	Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.	list	Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	modify	Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.
add	Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
delete	Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.								
list	Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
modify	Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
OPTIONS	<p>The smgroup authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smgroup command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>								
<i>auth_args</i>	<p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain.</p> <p>-D - -domain <i>domain</i></p> <p>Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that</p>								

changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | **-** *-hostname host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a “home toolbox” by default.

-l | **-** *-rolepassword role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | **-** *-password password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | **-** *-rolename role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | **-** *-username user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

-g *gid*

(Optional) Specifies the group ID for the new group. The group ID must be a non-negative decimal integer with a maximum value of 2MB (2,147,483,647). Group IDs 0–99 are reserved for the system and should be used with care. If you do not specify a *gid*, the system automatically assigns the next available *gid*. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.

-h

(Optional) Displays the command’s usage statement.

smgroup(1M)

- m *group_member1* -m *group_member2* . . .
(Optional) Specifies the new members to add to the group.
- n *group_name*
Specifies the name of the new group. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
- For subcommand `delete`:
 - h (Optional) Displays the command's usage statement.
 - n *group_name* Specifies the name of the group you want to delete.
- For subcommand `list`:
 - h (Optional) Displays the command's usage statement.
 - n *group_name* (Optional) Specifies the name of the group you want to list. If you do not specify a group name, all groups are listed.
- For subcommand `modify`:
 - h (Optional) Displays the command's usage statement.
 - m *group_member1* -m *group_member2* . . .
(Optional) Specifies the new members to add to the group.
 - n *group_name*
Specifies the name of the group you want to modify.
 - N *new_group*
(Optional) Specifies the new group name. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

EXAMPLES **EXAMPLE 1** Creating a test group

The following creates the `test_group` group entry with a group ID of 123 and adds `test_member1` and `test_member2` to the group:

```
./smgroup add -H myhost -p mypasswd -u root -- -n test_group \  
-m test_member1 -m test_member2 -g 123
```

EXAMPLE 2 Deleting a group

The following deletes `test_group`:

```
./smgroup delete -H myhost -p mypasswd -u root -- -n test_group
```

EXAMPLE 3 Displaying all groups

The following displays all groups in a three-column list showing the group name, group ID, and group members:

EXAMPLE 3 Displaying all groups *(Continued)*

```
./smgroup list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Displaying a group

The following displays the `group_1` data in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root -- -n group_1
```

EXAMPLE 5 Renaming a group

The following renames a group from `finance` to `accounting`:

```
./smgroup modify -H myhost -p mypasswd -u root -- \
-n finance -N accounting
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smgroup` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smgroup` command:

`/etc/group` Group file. See `group(4)`.

ATTRIBUTES

smaillist(1M)

NAME	smaillist – manage email alias entries								
SYNOPSIS	<code>/usr/sadm/bin/smaillist subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	<p>The smaillist command manages one or more email alias entries for the appropriate files in the local /etc files name service or a NIS or NIS+ name service.</p> <p><i>subcommands</i></p> <p>smaillist <i>subcommands</i> are:</p> <table><tr><td>add</td><td>Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr><tr><td>delete</td><td>Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.</td></tr><tr><td>list</td><td>Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr><tr><td>modify</td><td>Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr></table>	add	Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.	list	Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	modify	Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.
add	Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
delete	Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.								
list	Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
modify	Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
OPTIONS	<p>The smaillist authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smaillist command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p> <p><i>auth_args</i></p> <p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p>-D - -domain <i>domain</i></p> <p>Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that</p>								

changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | **-** *-hostname host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M)` **-B** option, or set your console preferences to load a “home toolbox” by default.

-l | **-** *-rolepassword role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | **-** *-password password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | **-** *-rolename role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | **-** *-username user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand **add**:

-a *address1 -a address2 . . .* (Optional) Specifies the new email address. See `sendmail(1M)`.

-h (Optional) Displays the command’s usage statement.

-n *alias_name* Specifies the name of the alias you want to add. See `sendmail(1M)`.

■ For subcommand **delete**:

-h (Optional) Displays the command’s usage statement.

-n *alias_name* Specifies the alias you want to delete.

■ For subcommand **list**:

smaillist(1M)

- h (Optional) Displays the command's usage statement.
- n *alias_name* (Optional) Specifies the name of the alias you want to display. If you do not specify an alias, all aliases are listed.
- For subcommand modify:
 - a *address1* -a *address2* . . . (Optional) Specifies new email address(es) to replace the existing one(s). See `sendmail(1M)`.
 - h (Optional) Displays the command's usage statement.
 - n *alias_name* (Optional) Specifies the name of the alias you want to modify.
 - N *new_alias_name* Specifies the new alias name. Use only when renaming an alias. See `sendmail(1M)`.

EXAMPLES

EXAMPLE 1 Creating an alias

The following creates the `coworkers` alias and adds the following member list: `bill@machine1`, `sue@machine2`, and `me@machine3` to the alias.

```
./smaillist add -H myhost -p mypasswd -u root -- -n coworkers \  
-a bill@machine1 -a sue@machine2 -a me@machine3
```

EXAMPLE 2 Deleting a mail alias

The following deletes the `my_alias` alias:

```
./smaillist delete -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 3 Displaying members of a mail alias

The following displays the list of members belonging to the `my_alias` alias:

```
./smaillist list -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 4 Displaying members of all mail aliases

The following displays the list of members belonging to all mail aliases:

```
./smaillist list -H myhost -p mypasswd -u root --
```

EXAMPLE 5 Renaming a mail alias

The following renames the `current_name` mail alias to `new_name`:

```
./smaillist modify -H myhost -p mypasswd -u root -- \  
-n current_name -N new_name
```

EXAMPLE 6 Redefining an address list

The following changes the recipients of the alias `my_alias` to `bill@machine1`. Any previous recipients are deleted from the alias.

```
./smaillist modify -H myhost -p mypasswd -u root -- \
    -n my_alias -a bill@machine1
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smaillist` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smaillist` command:

`/var/mail/aliases` Aliases for `sendmail(1M)`. See `aliases(4)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO

`sendmail(1M)`, `smc(1M)`, `aliases(4)`, `attributes(5)`, `environ(5)`

smmultiuser(1M)

NAME	smmultiuser – manage bulk operations on user accounts						
SYNOPSIS	<code>/usr/sadm/bin/smmultiuser subcommand [auth_args] - - [subcommand_args]</code>						
DESCRIPTION	<p>The <code>smmultiuser</code> command allows bulk operations on user entries in the local <code>/etc</code> filesystem or a NIS or NIS+ name service, using either an input file or piped input.</p> <p><i>Note:</i> Both input files and piped input contain a cleartext (non-encrypted) password for each new user entry.</p>						
<i>subcommands</i>	<p><code>smmultiuser</code> subcommands are:</p> <table><tr><td>add</td><td>Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr><tr><td>delete</td><td>Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr><tr><td>modify</td><td>Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand:<ol style="list-style-type: none">1. UserName (only under certain conditions; see Note 2 in NOTES).2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization.3. Description.4. Primary Group ID.5. Shell type.6. FullName.</td></tr></table>	add	Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	modify	Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand: <ol style="list-style-type: none">1. UserName (only under certain conditions; see Note 2 in NOTES).2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization.3. Description.4. Primary Group ID.5. Shell type.6. FullName.
add	Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.						
delete	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.						
modify	Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand: <ol style="list-style-type: none">1. UserName (only under certain conditions; see Note 2 in NOTES).2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization.3. Description.4. Primary Group ID.5. Shell type.6. FullName.						
OPTIONS	<p>The <code>smmultiuser</code> authentication arguments, <i>auth_args</i>, are derived from the <code>smc(1M)</code> arg set and are the same regardless of which subcommand you use. The <code>smmultiuser</code> command requires the Solaris Management Console to be initialized for the command to succeed (see <code>smc(1M)</code>). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the <code>- -</code> option.</p>						
<i>auth_args</i>	<p>The valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, <code>-trust</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code>.</p>						

- D** | - *--domain domain*
 Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is *nis*, *nisplus*, *dns*, *ldap*, or *file*; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note*: Do *not* use *nis+* for *nisplus*.)
- If you do not specify this option, the Solaris Management Console assumes the *file* default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
- H** | - *--hostname host_name:port*
 Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the *smc(1M)* **-B** option, or set your console preferences to load a "home toolbox" by default.
- l** | - *--rolepassword role_password*
 Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p** | - *--password password*
 Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r** | - *--rolename role_name*
 Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- *--trust*
 Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.
- If using piped input into any of the *smmultiuser* subcommands, it will now be necessary to use the **-** *--trust* option with the **-L logfile** option. See EXAMPLES.
- u** | - *--username user_name*
 Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- *--*
 This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **-** *--* option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

smmultiuser(1M)

- For subcommand `add`:
 - h (Optional) Displays the command's usage statement.
 - i *input_file* Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES.
 - L *logfile* (Optional) Specifies the full pathname to the text file that stores the command's success/failure data. *Note*: This text file is an ASCII—formatted log file; it is different from and unrelated to the output of the normal logging mechanism that also occurs within the Log Viewer tool. The -L *logfile* option is used to dump additional logging information to a text file.
- For subcommand `delete`:
 - h (Optional) Displays the command's usage statement.
 - i *input_file* Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES.
 - L *logfile* (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.
- For subcommand `modify`:
 - h (Optional) Displays the command's usage statement.
 - i *input_file* Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES. *Note*: When modifying passwords, use the pipedReader input, since it is more secure than keeping passwords in a file. See Note 1 in NOTES.
 - L *logfile* (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

OPERANDS The following operands are supported:

pipedReader You must include *pipedReader* if you do not specify an *input_file*. Include the pipedReader input immediately before the command. The pipedReader input must follow the `/etc/passwd` file format. See EXAMPLES. *Note*: Use the - `-trust` option when using pipedReader input with the -L *logfile* option to avoid the user prompt from the Security Alert Manager, which normally asks the user whether the log file should be created. Without the - `-trust` option, the

piped input is improperly taken as the answer to the prompt before the user can answer “Y” or “N”, and the logging operation will probably fail.

EXAMPLES

EXAMPLE 1 Creating multiple user accounts

The following reads in user account data from the `/tmp/foo` file and creates new user accounts on the local file system. The input file is formatted in the `/etc/passwd` format.

```
./smmultiuser add -H myhost -p mypasswd -u root -- -i /tmp/foo
```

EXAMPLE 2 Deleting multiple user accounts

The following reads in user account data from the `/tmp/foo` file and deletes the named user accounts from the local file system:

```
./smmultiuser delete -H myhost -p mypasswd -u root -- -i /tmp/foo
```

EXAMPLE 3 Creating a log file with piped input

The following example shows the use of the `smc(1M) - -trust` option that is required when creating a log file. It is applicable to the `delete` and `modify` subcommands also.

```
cat /tmp/users.txt | smmultiuser add --trust -- -L /tmp/mylog.txt
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smprofile` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smprofile` command:

`/etc/passwd` Contains the file format to use for the *input_file* and *piped_input*. See `passwd(4)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

smmultiuser(1M)

SEE ALSO smc(1M), passwd(4), attributes(5), environ(5)

NOTES

1. The file format used by both the `add` and `modify` subcommands is the `/etc/passwd` format. But there is an allowance for a mutated version of this file format that contains an extra field at the end of each line to be used for the Full Name. If the extra field is appended to the end of each line, it will be used for the Full Name value, but if it is omitted, it will be assumed that no Full Name modification is being done. The extra field is separated with a colon (:), just like all the other fields.

Example of regulation `/etc/passwd` entry:

```
rick2:x:101:10:description1:/home/rick2:/bin/sh
```

Example of `/etc/passwd` variant entry:

```
rick2:x:101:10:description1:/home/rick2:/bin/sh:Ricks_fullname
```

2. The modifies are all done based on lookups of the user name in the user tables. If a user name can not be found in this lookup, a secondary check will be made to see if the uid *and* Full Name can be found in the user tables. If they are both found, assume that a user rename has occurred. If neither can be found, assume that the user account does not exist and cannot be modified.
3. If no password is supplied, assume that there is no change to the password information. If a password is being changed, it should be supplied in cleartext as piped input, although this is not required. The password can be supplied in the input file also. Once read in, the password will be changed accordingly.

NAME	smossservice – manage OS services								
SYNOPSIS	<code>/usr/sadm/bin/smossservice subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	<p>The smossservice command manages OS services.</p> <p>smossservice subcommands are:</p> <table border="0"> <tr> <td style="padding-right: 20px;">add</td> <td>Adds the specified OS services.</td> </tr> <tr> <td>delete</td> <td>Deletes the specified OS services.</td> </tr> <tr> <td>list</td> <td>Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.</td> </tr> <tr> <td>patch</td> <td>Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.</td> </tr> </table>	add	Adds the specified OS services.	delete	Deletes the specified OS services.	list	Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.	patch	Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.
add	Adds the specified OS services.								
delete	Deletes the specified OS services.								
list	Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.								
patch	Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.								
OPTIONS	<p>The smossservice authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smossservice command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>								
<i>auth_args</i>	<p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain.</p> <p>-D - -domain <i>domain</i></p> <p>Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nis+, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.</p>								

smoservice(1M)

- H** | **-** *-hostname host_name:port*
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.
- l** | **-** *-rolepassword role_password*
Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p** | **-** *-password password*
Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r** | **-** *-rolename role_name*
Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u** | **-** *-username user_name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- **-**
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand add:

- h** (Optional) Displays the command's usage statement.
- o** *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- x** *mediapath=path* Specifies the full path to the Solaris CD image.
- x** *platform=platform* Specifies the OS service to add. The instruction architecture, machine class, OS, and version are given in the form:

instruction_set.machine_class.Solaris_os_versionfor

example, `sparc.sun4m.Solaris_8`

- x `cluster=cluster` Specifies the Solaris cluster to install. For example, `SUNWCall`.
- x `locale=locale[locale, . . .]` (Optional) Specifies the locales to install from the specified cluster. A comma-delimited list of locales can be specified.
- For subcommand `delete`:
 - h (Optional) Displays the command's usage statement.
 - o `os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
 - x `rmplatform=platform` Specifies the OS service to remove. The instruction architecture, machine class, OS, and version are given in the form:

instruction_set.machine_class.Solaris_os_version
example, `sparc.all.Solaris_8`. *Note:* Only a machine class of `all` is supported.
- For subcommand `list`:
 - h (Optional) Displays the command's usage statement.
 - o `os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- For subcommand `patch`:
 - a `patch_directory/patch_ID` Adds the specified patch, `patch_ID`, to the spool directory. `patch_directory` specifies the source path of the patch to be spooled which includes the patchid directory name. Patches are spooled to `/export/diskless/Patches/`. If the patch being added obsoletes an existing patch in the spool, the obsolete patch is moved to the archive area, `/export/diskless/Patches/Archive` (to be restored if this new patch is ever removed).
 - h (Optional) Displays the command's usage statement.

smoservice(1M)

- m** (Optional) Synchronizes spooled patches with offline copies of each diskless client OS service on the server. Spooled patches and applied patches are compared so that newly spooled patches can be installed and patches recently removed from the spool can be backed out. This option does not apply to patches directly to diskless client OS services or diskless clients; the **-u** option must be used to update the services and clients with the changes. Clients are not required to be down at this time, as all patching is done off line. *Note:* The server is fully available during this operation.
- P** Lists all currently spooled patches with an associated synopsis. The list is split up into sections detailing the patches for each OS and architecture in this format:
- ```
Solaris os_rell architecture1:
patchid Synopsis
patchid Synopsis
.....
Solaris os_rell architecture2:
patchid Synopsis
.....
```
- r *patchid*** Removes the specified patchid from the spool if it is not a requirement for any of the other patches in the spool. All archived patches that were obsoleted by the removed patch are restored to the spool.
- U** (Optional) Updates all diskless client OS services and diskless clients with any changes after synchronizing patches with the **-m** option. Clients must be brought down during this operation. Once execution has completed, each client should be booted again.

### EXAMPLES **EXAMPLE 1** Creating a new OS service

The following command adds an OS service for Solaris 8 for the sun4u machine class where the OS server is *not* using a name service:

```
example% /usr/sadm/bin/smoservice add -- \
-x mediapath=/net/imageserver/5.8/sparc \
-x platform=sparc.sun4u.Solaris_8 \
-x cluster=SUNWCXall -x locale=en_US
```

The following command adds an OS service for Solaris 8 for the sun4u machine class where the OS server is using NIS, the NIS server is nisserver, the OS server is osserver, and the port to which you connect on osserver is 898:

```
example% /usr/sadm/bin/smoservice add -D nis:/nisserver/my.domain.com -- \
 -H osserver:898 -- \
 -x mediapath=/net/imageserver/5.8/sparc \
 -x platform=sparc.sun4u.Solaris_8 \
 -x cluster=SUNWCXall -x locale=en_US \
 -o osserver
```

In the preceding example, the OS service is placed in /export on osserver, while the hosts.byaddr, ethers, and bootparams maps are updated on the NIS server.

#### EXAMPLE 2 Deleting an OS service

The following command deletes the OS service for Solaris 8 for the sun4u machine class where the OS server is using NIS, the NIS server is nisserver, and the OS server is osserver:

```
example% /usr/sadm/bin/smoservice delete \
 -D nis:/nisserver/my.domain.com -- \
 -x rmplatform=sparc.all.Solaris_8 \
 -o osserver
```

#### EXAMPLE 3 Listing installed OS services

The following command lists the OS services installed on the machine, osserver:

```
example% /usr/sadm/bin/smoservice list \
 -D file:/osserver/osserver -- -o osserver
```

#### ENVIRONMENT VARIABLES

See environ(5) for a description of the JAVA\_HOME environment variable, which affects the execution of the smoservice command. If this environment variable is not specified, the /usr/java1.2 location is used. See smc(1M).

#### EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

#### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

smoservice(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | smprofile – manage profiles in the prof_attr and exec_attr databases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>/usr/sadm/bin/smprofile subcommand [ auth_args ] - - [subcommand_args]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | The smprofile command manages one or more profiles in the prof_attr(4) or exec_attr(4) databases in the local /etc files name service or a NIS or NIS+ name service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>subcommands</i> | <p>smprofile <i>subcommands</i> are:</p> <p><b>add</b>                Adds a new profile (right) to the prof_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.</p> <p><b>delete</b>            Deletes a profile from the prof_attr(4) database, deletes all associated entries from the exec_attr(4) database, and deletes the assigned profile from the user_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.</p> <p><b>list</b>               Lists one or more profiles from the prof_attr(4) or exec_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.</p> <p><b>modify</b>            Modifies a profile in the prof_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.</p> |
| <b>OPTIONS</b>     | <p>The smprofile authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smprofile command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>                                                                                                                                                                                                                                                                                                                                         |
| <i>auth_args</i>   | <p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p>-D   - -domain <i>domain</i></p> <p>Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)</p>                                                                               |

## smprofile(1M)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

**-H** | **-** `-hostname` *host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

**-l** | **-** `-rolepassword` *role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-p** | **-** `-password` *password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-r** | **-** `-rolename` *role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

**-u** | **-** `-username` *user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

**-** **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

*subcommand\_args*

*Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

`-a` *addauth1* `-a` *addauth2* . . . (Optional) Specifies the authorization name(s) to add to the new profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. A "grant" authorization is one in which the lowest component of the authorization name is replaced by the word `grant`. For example, to grant some profile the `solaris.role.write` authorization, the administrator needs that authorization and also the

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | <code>solaris.role.grant</code> authorization. For more information on granting authorizations, see <code>auth_attr(4)</code> .                                                                                                                                                                                                                                                                                                                                                               |
| <code>-d description</code>                | Specifies the description of the new profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-h</code>                            | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-m html_help</code>                  | Specifies the HTML help file name for the new profile. The help file name must be put in the <code>/usr/lib/help/profiles/locale/C</code> directory.                                                                                                                                                                                                                                                                                                                                          |
| <code>-n name</code>                       | Specifies the name of the new profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-p addprof1 -p addprof2 . . .</code> | (Optional) Specifies the supplementary profile name(s) to add to the new profile.                                                                                                                                                                                                                                                                                                                                                                                                             |
| ■ For subcommand <code>delete</code> :     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-h</code>                            | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-n name</code>                       | Specifies the name of the profile you want to delete.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ■ For subcommand <code>list</code> :       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-h</code>                            | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-l</code>                            | (Optional) Displays the detailed output for each profile in a block of <code>key:value</code> pairs, followed by a blank line that delimits each profile block. Each <code>key:value</code> pair is displayed on a separate line. All the attributes associated with a profile from the <code>prof_attr</code> and <code>exec_attr</code> databases are displayed. If you do not specify this option, only the specified profile name(s) and associated profile description(s) are displayed. |
| <code>-n name1 -n name2 . . .</code>       | (Optional) Specifies the profile(s) that you want to display. If you do not specify a profile name, all profiles are displayed.                                                                                                                                                                                                                                                                                                                                                               |
| ■ For subcommand <code>modify</code> :     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-a addauth1 -a addauth2 . . .</code> | (Optional) Specifies the authorization name(s) to add to the profile. The administrator must currently have been granted each of the specified authorizations and must have the ability to grant each of those authorizations to other users or roles. For more information on granting authorizations, see <code>auth_attr(4)</code> .                                                                                                                                                       |
| <code>-d description</code>                | (Optional) Specifies the new description of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-h</code>                                          | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                                                                                          |
| <code>-m <i>html_help</i></code>                         | (Optional) Specifies the new HTML help file name of the profile. If you change this name, you must accordingly rename the help file name entered in the <code>/usr/lib/help/profiles/locale/C</code> directory.                                                                                                                                             |
| <code>-n <i>name</i></code>                              | Specifies the name of the profile you want to modify.                                                                                                                                                                                                                                                                                                       |
| <code>-p <i>addprof1</i> -p <i>addprof2</i> . . .</code> | (Optional) Specifies the supplementary profile name(s) to add to the profile. The administrator must have the <code>solaris.profmgr.assign</code> authorization to add any profile and the <code>solaris.profmgr.delegate</code> authorization to add any profile that has been assigned to the authenticated user.                                         |
| <code>-q <i>delprof1</i> -q <i>delprof2</i> . . .</code> | (Optional) Specifies the supplementary profile name(s) to delete from the profile. The administrator must have the <code>solaris.profmgr.assign</code> authorization to delete any profile and the <code>solaris.profmgr.delegate</code> authorization to delete any profile that has been assigned to the authenticated user.                              |
| <code>-r <i>delauth1</i> -r <i>delauth2</i> . . .</code> | (Optional) Specifies the authorization name(s) to delete from the profile. The administrator must have the <code>solaris.profmgr.write</code> authorization and must have the corresponding "grant" authorization. For more information about "grant" authorizations, see the <code>-a</code> option description for the <code>add</code> subcommand above. |

### EXAMPLES

#### EXAMPLE 1 Creating a new profile

The following creates a new User Manager profile on the local file system. The new profile description is Manage users and groups, and the authorizations assigned are `solaris.admin.usermgr.write` and `solaris.admin.usermgr.read`. The supplementary profile assigned is Operator. The help file name is `RtUserMgmt.html`.

```
./smprofile add -H myhost -p mypasswd -u root -- -n "User Manager" \
-d "Manage users and groups" -a solaris.admin.usermgr.write \
-a solaris.admin.usermgr.read -p Operator -m RtUserMgmt.html
```

**EXAMPLE 2** Deleting a profile

The following deletes the `User Manager` profile from the local file system:

```
./smprofile delete -H myhost -p mypasswd -u root -- -n "User Manager"
```

**EXAMPLE 3** Listing all profiles

The following lists all profiles and their associated profile descriptions on the local file system.

```
./smprofile list -H myhost -p mypasswd -u root --
```

**EXAMPLE 4** Modifying a profile

The following modifies the `User Manager` profile on the local file system. The new profile description is `Manage world`, the new authorization assignment is `solaris.admin.usermgr.*` authorizations, and the new supplementary profile assignment is `All`. (The `-a` option argument must be enclosed in double quotes when the wildcard character (\*) is used.)

```
./smprofile modify -H myhost -p mypasswd -u root -- -n "User Manager" \
-d "Manage world" -a "solaris.admin.usermgr.*" -p All
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smprofile` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**FILES**

The following files are used by the `smprofile` command:

|                                      |                                                                   |
|--------------------------------------|-------------------------------------------------------------------|
| <code>/etc/security/exec_attr</code> | Execution profiles database. See <code>exec_attr(4)</code> .      |
| <code>/etc/security/prof_attr</code> | Profile description database. See <code>prof_attr(4)</code> .     |
| <code>/etc/user_attr</code>          | Extended user attribute database. See <code>user_attr(4)</code> . |

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

smprofile(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

| <b>NAME</b>        | smrole – manage roles and users in role accounts                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <code>/usr/sadm/bin/smrole subcommand [ auth_args ] - - [subcommand_args]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | The smrole command manages roles and adds or deletes users in role accounts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>subcommands</i> | <p>smrole <i>subcommands</i> are:</p> <p><b>add</b>                 Adds a new role entry. To add an entry, the administrator must have the <code>solaris.role.write</code> authorization.</p> <p><b>delete</b>               Deletes one or more roles. To delete an entry, the administrator must have the <code>solaris.role.write</code> authorization.</p> <p><b>list</b>                 Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</p> <p><b>modify</b>               Adds or deletes users from a role account. To modify an entry, the administrator must have the <code>solaris.role.write</code> authorization.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The smrole authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smrole command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>auth_args</i>   | <p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p><b>-D   - -domain <i>domain</i></b><br/> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)</p> <p>If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.</p> <p><b>-H   - -hostname <i>host_name:port</i></b><br/> Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i>, the system connects to the default port, 898. If you do not specify</p> |

## smrole(1M)

*host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l` | `-` `-rolepassword` *role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `-` `-password` *password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `-` `-rolename` *role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `-` `-username` *user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`-` `-`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

### *subcommand\_args*

*Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

#### ■ For subcommand `add`:

- `-a` *adduser1 -a adduser2 . . .* (Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization.
- `-c` *comment* (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).
- `-d` *dir* (Optional) Specifies the home directory of the new role, limited to 1024 characters.
- `-F` *full\_name* (Optional) Specifies the full, descriptive name of the role. The *full\_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
- `-G` *group1 -G group2 . . .* (Optional) Specifies the new role's supplementary group membership in the system group database

with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).

- h (Optional) Displays the command's usage statement.
- n *rolename* Specifies the name of the role you want to create.
- p *addprof1* -p *addprof2* . . . (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
- P *password* (Optional) Specifies the role's password. The *password* can contain up to eight characters. If you do not specify a password, the system prompts you for one. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password using the -P option, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. However, if you do not specify a password (and the system prompts you for one), the echo is turned off when you type in the password.
- s *shell* (Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcsh` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
- u *uid* (Optional) Specifies the ID of the role you want to add. If you do not specify this option, the system assigns the next available unique ID greater than 100.
- x *autohome=Y|N* (Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/login name`.
- x *perm=home\_perm* (Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is 0775.
- x *serv=homedir\_server* (Optional) If -D is `nis`, `nisplus`, or `ldap`, use this option to specify the name of the server where the user's home directory resides. Users created in a

## smrole(1M)

local scope must have their home directory server created on their local machines.

■ For subcommand `delete`:

- `-h` (Optional) Displays the command's usage statement.
- `-n rolename1 -n rolename2 . . .` Specifies the name of the role(s) you want to delete.

■ For subcommand `list`:

- `-h` (Optional) Displays the command's usage statement.
- `-l` (Optional) Displays the output for each user in a block of *key:value* pairs (for example, `user name:root`), followed by a blank line that delimits each user block. Each *key:value* pair is displayed on a separate line. The keys are: `autohome setup`, `comment`, `home directory`, `login shell`, `primary group`, `secondary groups`, `server`, `user ID (UID)`, and `user name`.
- `-n role1 -n role2 . . .` (Optional) Specifies the role(s) that you want to list. If you do not specify a role name, all roles are listed.

■ For subcommand `modify`:

- `-a adduser1 -a adduser2 . . .` (Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization, or must have the `solaris.role.delegate` authorization and be a member of the role being modified.
- `-c comment` (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).
- `-d dir` (Optional) Specifies the home directory of the new role, limited to 1024 characters.
- `-F full_name` (Optional) Specifies the full, descriptive name of the role. The *full\_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
- `-G group1 -G group2 . . .` (Optional) Specifies the new role's secondary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).

|                                             |                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                          | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                                                                                                                           |
| -n <i>rolename</i>                          | Specifies the name of the role you want to modify.                                                                                                                                                                                                                                                                                                                                           |
| -N <i>new_rolename</i>                      | (Optional) Specifies the new name of the role.                                                                                                                                                                                                                                                                                                                                               |
| -p <i>addprof1</i> -p <i>addprof2</i> . . . | (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the <code>solaris.profmgr.assign</code> or <code>solaris.profmgr.delegate</code> authorization.                                                                                                                                                                           |
| -P <i>password</i>                          | (Optional) Specifies the role's password. The <i>password</i> can contain up to eight characters. To set the password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization. <i>Note:</i> When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. |
| -q <i>delprof1</i> -q <i>delprof2</i> . . . | (Optional) Specifies the profile(s) to delete from the role.                                                                                                                                                                                                                                                                                                                                 |
| -r <i>deluser1</i> -r <i>deluser2</i> . . . | (Optional) Specifies the user name(s) to delete from the role.                                                                                                                                                                                                                                                                                                                               |
| -s <i>shell</i>                             | (Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are <code>/bin/pfcsh</code> (C shell), <code>/bin/pfksh</code> (Korn shell), and <code>/bin/pfsh</code> (Bourne shell), the default.                                                                                                                                                  |
| -x <i>autohome=Y N</i>                      | (Optional) Sets the role's home directory. The home directory path in the password entry is set to <code>/home/login_name</code> .                                                                                                                                                                                                                                                           |
| -x <i>perm=home_perm</i>                    | (Optional) Sets the permissions on the role's home directory. <i>perm</i> is interpreted as an octal number, and the default is 0775.                                                                                                                                                                                                                                                        |

**EXAMPLES**    **EXAMPLE 1** Creating a role account

The following creates the `role1` account with a full name of Engineering Admin and a password of `abc123` on the local file system, and assigns `user1` and `user2` to the role. This role has Name Service Security and Audit Review rights. The system assigns the next available unique UID greater than 100.

```
./smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -a user1 -a user2 \
-p "Name Service Security" -p "Audit Review"
```

## smrole(1M)

### EXAMPLE 2 Deleting role accounts

The following deletes the `role1` and `role2` accounts from the local file system.

```
./smrole delete -H myhost -p mypasswd -u root -- -n role1 -n role2
```

### EXAMPLE 3 Listing role accounts

The following lists all role accounts on the local file system in summary form.

```
./smrole list -H myhost -p mypasswd -u root --
```

### EXAMPLE 4 Modifying a role account

The following modifies the `role1` account so the role defaults to the Korn shell, includes the `user3` account, and does not include the `user2` account.

```
./smrole modify -H myhost -p mypasswd -u root -- -n role1 \
-s /bin/pfksh -a user3 -r user2
```

## ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smrole` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

## EXIT STATUS

The following exit values are returned:

- |   |                                                                           |
|---|---------------------------------------------------------------------------|
| 0 | Successful completion.                                                    |
| 1 | Invalid command syntax. A usage message displays.                         |
| 2 | An error occurred while executing the command. An error message displays. |

## FILES

The following files are used by the `smrole` command:

|                                        |                                                                           |
|----------------------------------------|---------------------------------------------------------------------------|
| <code>/etc/aliases</code>              | Mail aliases. See <code>aliases(4)</code> .                               |
| <code>/etc/auto_home</code>            | Automatic mount points. See <code>automount(1M)</code> .                  |
| <code>/etc/group</code>                | Group file. See <code>group(4)</code> .                                   |
| <code>/etc/passwd</code>               | Password file. See <code>passwd(4)</code> .                               |
| <code>/etc/security/policy.conf</code> | Configuration file for security policy. See <code>policy.conf(4)</code> . |
| <code>/etc/shadow</code>               | Shadow password file. See <code>shadow(4)</code> .                        |
| <code>/etc/user_attr</code>            | Extended user attribute database. See <code>user_attr(4)</code> .         |

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

smrole(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**SEE ALSO** automount(1M), smc(1M), aliases(4), group(4), passwd(4), policy.conf(4), shadow(4), user\_attr(4), attributes(5), environ(5)

smrsh(1M)

**NAME** smrsh – restricted shell for sendmail

**SYNOPSIS** **smrsh** -c *command*

**DESCRIPTION** The **smrsh** program is intended as a replacement for the **sh** command in the program in **sendmail(1M)** configuration files. The **smrsh** program sharply limits commands that can be run using the |program syntax of **sendmail**. This improves overall system security. **smrsh** limits the set of programs that a programmer can execute, even if **sendmail** runs a program without going through an alias or forward file.

Briefly, **smrsh** limits programs to be in the directory **/var/adm/sm.bin**, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters: **, , < , > , | , ; , & , \$ , \r (RETURN)**, or **\n (NEWLINE)** on the command line to prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to **/usr/ucb/vacation**, **/usr/bin/vacation**, **/home/server/mydir/bin/vacation**, and **vacation** all actually forward to **/var/adm/sm.bin/vacation**.

System administrators should be conservative about populating **/var/adm/sm.bin**. Reasonable additions are utilities such as **vacation(1)** and **procmail**. Never include any shell or shell-like program (for example, **perl**) in the **sm.bin** directory. This does not restrict the use of **shell** or **perl** scrips in the **sm.bin** directory (using the **#!** syntax); it simply disallows the execution of arbitrary programs.

**OPTIONS** The following options are supported:

-c *command* Where *command* is a valid command, executes *command*.

**FILES** **/var/adm/sm.bin** directory for restricted programs

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE  |
|----------------|------------------|
| Availability   | SUNWcsr, SUNWcsu |

| <b>NAME</b>        | smuser – manage user entries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/sadm/bin/smuser subcommand [ auth_args ] - - [subcommand_args]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | The smuser command manages one or more user entries in the local <code>/etc</code> filesystem or a NIS or NIS+ target name service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>subcommands</i> | <p>smuser <i>subcommands</i> are:</p> <p><b>add</b>                Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</p> <p><b>delete</b>             Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.</p> <p><b>list</b>                Lists one more user entries from the appropriate files. To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</p> <p><b>modify</b>            Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</p> |
| <b>OPTIONS</b>     | <p>The smuser authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smuser command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>auth_args</i>   | <p>The valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code> with the <i>domain</i> argument.</p> <p><code>-D   - --domain domain</code><br/> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i>:<i>/host_name/domain_name</i>, where <i>type</i> is <code>nis</code>, <code>nisplus</code>, <code>dns</code>, <code>ldap</code>, or <code>file</code>; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use <code>nis+</code> for <code>nisplus</code>.)</p>                                                                                       |

## smuser(1M)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

**-H** | **-** `--hostname` *host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

**-l** | **-** `--rolepassword` *role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-p** | **-** `--password` *password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-r** | **-** `--rolename` *role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

**-u** | **-** `--username` *user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

**-** **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

*subcommand\_args*

*Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

**-c** *comment*

(Optional) Includes a short description of the login, which is typically the user's name. Consists of a string of up to 256 printable characters, excluding the colon (:).

**-d** *dir*

(Optional) Specifies the home directory of the new user, limited to 1024 characters.

**-e** *ddmmyyyy*

(Optional) Specifies the expiration date for a login. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a

- null value (" ") to indicate that the login is always valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- f *inactive* (Optional) Specifies the maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. Enter zero to indicate that the login account is always active.
  - F *full\_name* (Optional) Specifies the full, descriptive name of the user. The *full\_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
  - g *group* (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
  - G *group1* -G *group2* . . . (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the -g and -G options are ignored.
  - h (Optional) Displays the command's usage statement.
  - n *login* Specifies the new user's login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
  - P *password* (Optional) Specifies up to an eight-character password assigned to the user account. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
  - s *shell* (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).
  - t *template* (Optional) Specifies a template, created using the User Manager tool, that contains a set of pre-defined user attributes. You may have entered a name service server in the template. However, when a user is actually

## smuser(1M)

|                                        |                                                                                                                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                        | added with this template, if a name service is unavailable, the user's local server will be used for both the Home Directory Server and Mail Server.                                                                                      |
| -u <i>uid</i>                          | (Optional) Specifies the user ID of the user you want to add. If you do not specify this option, the system assigns the next available unique user ID greater than 100.                                                                   |
| -x <i>autohome</i> =Y N                | (Optional) Sets the home directory to automount if set to Y. The user's home directory path in the password entry is set to <i>/home/login name</i> .                                                                                     |
| -x <i>mail</i> = <i>mail_server</i>    | (Optional) Specifies the host name of the user's mail server, and creates a mail file on the server. Users created in a local scope must have a mail server created on their local machines.                                              |
| -x <i>perm</i> = <i>home_perm</i>      | (Optional) Sets the permissions on the user's home directory. <i>perm</i> is interpreted as an octal number, and the default is 0775.                                                                                                     |
| -x <i>pwmax</i> = <i>days</i>          | (Optional) Specifies the maximum number of days that the user's password is valid. The administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization.                                                                 |
| -x <i>pwmin</i> = <i>days</i>          | (Optional) Specifies the minimum number of days between user password changes. The administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization.                                                                     |
| -x <i>pwwarn</i> = <i>days</i>         | (Optional) Specifies the number of days relative to <i>pwmax</i> that the user is warned about password expiration prior to the password expiring. The administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization. |
| -x <i>serv</i> = <i>homedir_server</i> | (Optional) Specifies the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.                                                |
| ■ For subcommand <code>delete</code> : |                                                                                                                                                                                                                                           |
| -h                                     | (Optional) Displays the command's usage statement.                                                                                                                                                                                        |
| -n <i>login1</i>                       | Specifies the login name of the user you want to delete.                                                                                                                                                                                  |
| -n <i>login2</i> . . .                 | (Optional) Specifies the additional login name(s) of the user(s) you want to delete.                                                                                                                                                      |
| ■ For subcommand <code>list</code> :   |                                                                                                                                                                                                                                           |
| -h                                     | (Optional) Displays the command's usage statement.                                                                                                                                                                                        |

- l Displays the output for each user in a block of *key:value* pairs (for example, user name : root) followed by a blank line to delimit each user block. Each *key:value* pair is displayed on a separate line. The keys are: autohome setup, comment, days to warn, full name, home directory, home directory permissions, login shell, mail server, max days change, max days inactive, min days change, password expires, password type, primary group, rights, roles, secondary groups, server, user ID (UID), and user name.
- n *login1* Specifies the login name of the user you want to list.
- n *login2* ... (Optional) Specifies the additional login name(s) of the user(s) you want to list.
- For subcommand modify:
  - a *addrole1* -a *addrole2* ... (Optional) Specifies the role(s) to add to the user account. To assign a role to a user, the administrator must have the `solaris.role.assign` authorization or must have the `solaris.role.delegate` authorization and be a member of each of the roles specified.
  - c *comment* (Optional) Describes the changes you made to the user account. Consists of a string of up to 256 printable characters, excluding the colon (:).
  - d *description* (Optional) Specifies the user's home directory, limited to 1024 characters.
  - e *ddmmyyyy* (Optional) Specifies the expiration date for a login in a format appropriate to the locale. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (" ") to indicate that the login is always valid.
  - f *inactive* (Optional) Specifies the maximum number of days allowed between uses of a login ID before the ID is declared invalid. Normal values are positive integers. Specify zero to indicate that the login account is always active.
  - F *full\_name* (Optional) Specifies the full, descriptive name of the user. The *full\_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
  - g *group* (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.

|                                            |                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-G group1 -G group2 . . .</code>     | (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the <code>-g</code> and <code>-G</code> options are ignored.                          |
| <code>-h</code>                            | (Optional) Displays the command's usage statement.                                                                                                                                                                                                                                        |
| <code>-n name</code>                       | Specifies the user's current login name.                                                                                                                                                                                                                                                  |
| <code>-N new_name</code>                   | (Optional) Specifies the user's new login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.                                                                                      |
| <code>-p addprof1 -p addprof2 . . .</code> | (Optional) Specifies the profile(s) to add to the user account. To assign a profile to a user, the administrator must have the <code>solaris.profmgr.assign</code> or <code>solaris.profmgr.delegate</code> authorization.                                                                |
| <code>-P password</code>                   | (Optional) Specifies up to an eight-character password assigned to the user account.<br><br>When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.                             |
| <code>-q delprof1 -q delprof2 . . .</code> | (Optional) Specifies the profile(s) to delete from the user account.                                                                                                                                                                                                                      |
| <code>-r delrole1 -r delrole2 . . .</code> | (Optional) Specifies the role(s) to delete from the user account.                                                                                                                                                                                                                         |
| <code>-s shell</code>                      | (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, <code>/bin/csh</code> (C shell), <code>bin/ksh</code> (Korn shell), and the default, <code>/bin/sh</code> (Bourne shell).l) |
| <code>-x autohome=Y N</code>               | (Optional) Sets up the home directory to automount if set to <code>Y</code> . The user's home directory path in the password entry is set to <code>/home/login name</code> .                                                                                                              |
| <code>-x pwmax=days</code>                 | (Optional) Specifies the maximum number of days that the user's password is valid.                                                                                                                                                                                                        |
| <code>-x pwmin=days</code>                 | (Optional) Specifies the minimum number of days between password changes.                                                                                                                                                                                                                 |
| <code>-x pwwarn=days</code>                | (Optional) Specifies the number of days relative to <code>pwmax</code> that the user is warned about password                                                                                                                                                                             |

expiration before the password expires.

#### EXAMPLES **EXAMPLE 1** Creating a new user account

The following creates a new user account on the local file system. The account name is `user1`, and the full name is `Joe Smith`. The comment field verifies that the account is for Joe Smith. The system will assign the next available user ID greater than 100 to this account. There is no password set for this account, so when Joe Smith logs in for the first time, he will be prompted to enter a password.

```
./smuser add -H myhost -p mypasswd -u root -- -F "Joe Smith" \
 -n user1 -c "Joe's account"
```

#### **EXAMPLE 2** Deleting a user account

The following deletes the `user1` account from the local file system:

```
./smuser delete -H myhost -p mypasswd -u root -- -n user1
```

#### **EXAMPLE 3** Listing all user accounts

The following lists all user accounts on the local file system in summary form:

```
./smuser list -H myhost -p mypasswd -u root --
```

#### **EXAMPLE 4** Modifying a user account

The following modifies the `user1` account to default to a Korn shell, and assigns the account to the `qa_group` secondary group.

```
./smuser modify -H myhost -p mypasswd -u root -- -n user1 \
 -s /bin/ksh -G qa_group
```

#### ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smuser` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

#### EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

#### FILES

The following files are used by the `smuser` command:

`/etc/aliases` Mail aliases. See `aliases(4)`.

smuser(1M)

| <b>DESCRIPTION</b> | <p>The Master Agent, <code>snmpdx</code>, is the main component of Solstice Enterprise Agent technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.</p> <p>Upon invocation, <code>snmpdx</code> reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-a filename</code> Specify the full path of the access control file used by the Master Agent. The default access control file is <code>/etc/snmp/conf/snmpdx.acl</code>.</li> <li><code>-c config-dir</code> Specify the full path of the directory containing the Master Agent configuration files. The default directory is <code>/etc/snmp/conf</code>.</li> <li><code>-d debug-level</code> Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.</li> <li><code>-h</code> Help. Print the command line usage.</li> <li><code>-i filename</code> Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <code>/var/snmp/snmpdx.st</code>.</li> <li><code>-m GROUP   -m SPLIT</code> Specify the mode to use for forwarding of SNMP requests. <ul style="list-style-type: none"> <li><code>GROUP</code> Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.</li> <li><code>SPLIT</code> Each variable in the incoming request results in one send-request to each subagent.</li> </ul> </li> </ul> |

## snmpdx(1M)

- The default is `GROUP`.
- `-o filename` Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is `/etc/snmp/conf/enterprises.oid`.
  - `-p port` Specify the port number. The default port number is 161.
  - `-r filename` Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is `/etc/snmp/conf/snmpdx.rsrc`.
  - `-y` Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

**FILES**

- `/var/snmp/conf/enterprises.oid`  
Enterprise-name OID map
- `/var/snmp/conf/snmpdx.acl`  
Access control file
- `/var/snmp/conf/snmpdx.rsrc`  
Resource configuration file
- `/var/snmp/snmpdx.st`  
Master Agent status file
- `/var/snmp/mib/snmpdx.mib`  
Master Agent MIB file

**EXIT STATUS** The following error values are returned:

- 0 Successful completion.
- non-zero An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>                     | <code>/usr/lib/dmi/snmpXdmid -s hostname [-h] [-c config-dir] [-d debug-level]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                |                                                                          |                                   |                                                                                      |                                |                                                              |                                     |  |  |                                                             |  |                                                                                |
| <b>DESCRIPTION</b>                  | <p>The <code>snmpXdmid</code> utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (<code>snmpdx(1M)</code>) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to <code>snmpdx</code>. By default, <code>snmpXdmid</code> also forwards the DMI indications as SNMP traps to <code>snmpdx</code>. The feature is configurable and can be disabled by setting <code>TRAP_FORWARD_TO_MAGENT=0</code> in the <code>snmpXdmid</code> configuration file, <code>snmpXdmid.conf</code>.</p> <p>This subagent runs as a daemon in the system. The subagent uses a set of <code>.MAP</code> files located in <code>/var/dmi/map</code> to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, <code>miftoMIB</code>. They are read by <code>snmpXdmid</code> when a corresponding MIF file gets registered with the DMI Service Provider (<code>dmispd(1M)</code>).</p> <p>The <code>snmpXdmid.conf</code> file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>WARNING_TIMESTAMP</code></td> <td>Indication subscription expiration, warning time.</td> </tr> <tr> <td style="padding-right: 20px;"><code>EXPIRATION_TIMESTAMP</code></td> <td>Indication subscription expiration timestamp.</td> </tr> <tr> <td style="padding-right: 20px;"><code>FAILURE_THRESHOLD</code></td> <td>DMISP retries before dropping indication due to comm errors.</td> </tr> <tr> <td style="padding-right: 20px;"><code>TRAP_FORWARD_TO_MAGENT</code></td> <td></td> </tr> <tr> <td></td> <td style="padding-left: 40px;">0                    Drop indication at the subagent level.</td> </tr> <tr> <td></td> <td style="padding-left: 40px;">non-zero            Forward indications as SNMP traps to <code>snmpdx</code>.</td> </tr> </table> <p>By default, the configuration file <code>snmpXdmid.conf</code> is located in the <code>/etc/dmi/conf</code> directory. You can specify an alternative directory with the <code>-c</code> option.</p> | <code>WARNING_TIMESTAMP</code> | Indication subscription expiration, warning time.                        | <code>EXPIRATION_TIMESTAMP</code> | Indication subscription expiration timestamp.                                        | <code>FAILURE_THRESHOLD</code> | DMISP retries before dropping indication due to comm errors. | <code>TRAP_FORWARD_TO_MAGENT</code> |  |  | 0                    Drop indication at the subagent level. |  | non-zero            Forward indications as SNMP traps to <code>snmpdx</code> . |

| <b>NAME</b>        | snoop – capture and inspect network packets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>snoop</b> [-aqrCDNPSvV] [-t [r   a   d]] [-c <i>maxcount</i> ] [-d <i>device</i> ]<br>[-i <i>filename</i> ] [-n <i>filename</i> ] [-o <i>filename</i> ] [-p <i>first</i> [, <i>last</i> ]] [-s <i>snaplen</i> ]<br>[-x <i>offset</i> [, <i>length</i> ]] [ <i>expression</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>snoop captures packets from the network and displays their contents. snoop uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file (which is <i>RFC 1761</i>-compliant) for later inspection.</p> <p>snoop can display packets in a single-line summary form or in verbose multi-line forms. In summary form, only the data pertaining to the highest level protocol is displayed. For example, an NFS packet will have only NFS information displayed. The underlying RPC, UDP, IP, and ethernet frame information is suppressed but can be displayed if either of the verbose options are chosen.</p> <p>snoop requires an interactive interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>-C List the code generated from the filter expression for either the kernel packet filter, or snoop's own filter.</p> <p>-D Display number of packets dropped during capture on the summary line.</p> <p>-N Create an IP address-to-name file from a capture file. This must be set together with the -i option that names a capture file. The address-to-name file has the same name as the capture file with .names appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a .names file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.</p> <p>-P Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.</p> <p>-S Display size of the entire ethernet frame in bytes on the summary line.</p> <p>-V Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through <code>grep</code> to extract packets of interest. For example, to</p> |

## snoop(1M)

|                                   |                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | view only RPC summary lines, enter the following:<br>example# <b>snoop -i rpc.cap -V   grep RPC</b>                                                                                                                                                                                                                                                                          |
| -a                                | Listen to packets on /dev/audio (warning: can be noisy).                                                                                                                                                                                                                                                                                                                     |
| -c <i>maxcount</i>                | Quit after capturing <i>maxcount</i> packets. Otherwise keep capturing until there is no disk left or until interrupted with Control-C.                                                                                                                                                                                                                                      |
| -d <i>device</i>                  | Receive packets from the network using the interface specified by <i>device</i> , for example, <i>le0</i> or <i>hme0</i> . The program <code>netstat(1M)</code> , when invoked with the <code>-i</code> flag, lists all the interfaces that a machine has. Normally, <code>snoop</code> will automatically choose the first non-loopback interface it finds.                 |
| -i <i>filename</i>                | Display packets previously captured in <i>filename</i> . Without this option, <code>snoop</code> reads packets from the network interface. If a <i>filename.names</i> file is present, it is automatically loaded into the <code>snoop</code> IP address-to-name mapping table (See <code>-N</code> flag).                                                                   |
| -n <i>filename</i>                | Use <i>filename</i> as an IP address-to-name mapping table. This file must have the same format as the <code>/etc/hosts</code> file (IP address followed by the hostname).                                                                                                                                                                                                   |
| -o <i>filename</i>                | Save captured packets in <i>filename</i> as they are captured. (This <i>filename</i> is referred to as the "capture file".) The format of the capture file is RFC 1761-compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file <code>/dev/null</code> . |
| -p <i>first</i> [ , <i>last</i> ] | Select one or more packets to be displayed from a capture file. The <i>first</i> packet in the file is packet number 1.                                                                                                                                                                                                                                                      |
| -q                                | When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.                                                                                                                                                                                                                                                  |
| -r                                | Do not resolve the IP address to the symbolic name. This prevents <code>snoop</code> from generating network traffic while capturing and displaying packets. However, if the <code>-n</code> option is used, and an address is found in the mapping file, its corresponding name will be used.                                                                               |
| -s <i>snaplen</i>                 | Truncate each packet after <i>snaplen</i> bytes. Usually the whole packet is captured. This option is useful if only                                                                                                                                                                                                                                                         |

|                 |                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 |                                     | certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a <i>snaplen</i> of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a <i>snaplen</i> of 80 bytes. NFS headers can be captured in 120 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                 | <code>-t [ r   a   d ]</code>       | Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in <i>d</i> (delta) format (the time since receiving the previous packet). Option <i>a</i> (absolute) gives wall-clock time. Option <i>r</i> (relative) gives time relative to the first packet displayed. This can be used with the <code>-p</code> option to display time relative to any selected packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                 | <code>-v</code>                     | Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                 | <code>-x offset [ , length ]</code> | Display packet data in hexadecimal and ASCII format. The <i>offset</i> and <i>length</i> values select a portion of the packet to be displayed. To display the whole packet, use an <i>offset</i> of 0. If a <i>length</i> value is not provided, the rest of the packet is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPERANDS</b> | <i>expression</i>                   | <p>Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.</p> <p>Given a filter expression, <code>snoop</code> generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to <code>snoop</code>. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or <code>snoop</code>. The kernel packet filter has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, <code>snoop</code> tries to split the filter and do as much filtering in the kernel as possible. The remaining filtering is done by the packet filter for <code>snoop</code>. The <code>-C</code> flag can be used to view generated code for either the packet filter for the kernel or the packet filter for</p> |

## snoop(1M)

snoop. If packets are read from a capture file using the `-i` option, only the packet filter for `snoop` is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to Example 2 for information about setting up more efficient filters.

The primitives are:

### *host hostname*

True if the source or destination address is that of *hostname*. The *hostname* argument may be a literal address. The keyword `host` may be omitted if the name does not conflict with the name of another expression primitive. For example, "pinky" selects packets transmitted to or received from the host `pinky`, whereas "pinky and dinky" selects packets exchanged between hosts `pinky` AND `dinky`.

The type of address used depends on the primitive which precedes the `host` primitive. The possible qualifiers are "inet", "inet6", "ether", or none. These three primitives are discussed below. Having none of the primitives present is equivalent to "inet host hostname or inet6 host hostname". In other words, `snoop` tries to filter on all IP addresses associated with *hostname*.

### *inet or inet6*

A qualifier that modifies the `host` primitive that follows. If it is *inet*, then `snoop` tries to filter on all IPv4 addresses returned from a name lookup. If it is *inet6*, `snoop` tries to filter on all IPv6 addresses returned from a name lookup.

### *ipaddr or etheraddr*

Literal addresses, both IP dotted and ethernet colon are recognized. For example,

- "129.144.40.13" matches all packets with that IP ;
- "2::9255:a00:20ff:fe73:6e35" matches all packets with that IPv6 address as source or destination;
- "8:0:20:f:b1:51" matches all packets with the ethernet address as source or destination.

An ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the ethernet address is

"aa:0:45:23:52:44", then specify it by add a leading zero to make it "0aa:0:45:23:52:44".

**from or src**

A qualifier that modifies the following *host*, *net*, *ipaddr*, *etheraddr*, *port* or *rpc* primitive to match just the source address, port, or RPC reply.

**to or dst**

A qualifier that modifies the following *host*, *net*, *ipaddr*, *etheraddr*, *port* or *rpc* primitive to match just the destination address, port, or RPC call.

**ether**

A qualifier that modifies the following *host* primitive to resolve a name to an ethernet address. Normally, IP address matching is performed.

**ethertype *number***

True if the ethernet type field has value *number*. Equivalent to "ether[12:2] = *number*".

**ip, ip6, arp, rarp, pppoe, pppoes**

True if the packet is of the appropriate ethertype.

**pppoe**

True if the ethertype of the packet is either pppoe or pppoes.

**broadcast**

True if the packet is a broadcast packet. Equivalent to "ether[2:4] = 0xffffffff".

**multicast**

True if the packet is a multicast packet. Equivalent to "ether[0] & 1 = 1".

**apple**

True if the packet is an Apple Ethertalk packet. Equivalent to "ethertype 0x809b or ethertype 0x803f".

**decnet**

True if the packet is a DECNET packet.

**greater *length***

True if the packet is longer than *length*.

**less *length***

True if the packet is shorter than *length*.

**udp, tcp, icmp, icmp6, ah, esp**

True if the IP or IPv6 protocol is of the appropriate type.

*net net*

True if either the IP source or destination address has a network number of *net*. The *from* or *to* qualifier may be used to select packets for which the network number occurs only in the source or destination address.

*port port*

True if either the source or destination port is *port*. The *port* may be either a port number or name from */etc/services*. The *tcp* or *udp* primitives may be used to select TCP or UDP ports only. The *from* or *to* qualifier may be used to select packets for which the *port* occurs only as the source or destination.

*rpc prog [ , vers [ , proc ] ]*

True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The *prog* may be either the name of an RPC protocol from */etc/rpc* or a program number. The *vers* and *proc* may be used to further qualify the program *version* and *procedure* number, for example, "*rpc nfs, 2, 0*" selects all calls and replies for the NFS null procedure. The *to* or *from* qualifier may be used to select either call or reply packets only.

*ldap*

True if the packet is an LDAP packet on port 389.

*gateway host*

True if the packet used *host* as a gateway, that is, the ethernet source or destination address was for *host* but not the IP address. Equivalent to "*ether host host and not host host*".

*nofrag*

True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to "*ip[6:2] & 0x1fff = 0*".

*expr relop expr*

True if the relation holds, where *relop* is one of *>*, *<*, *>=*, *<=*, *=*, *!=*, and *expr* is an arithmetic expression composed of numbers, packet field selectors, the *length* primitive, and arithmetic operators *+*, *-*, *\**, *&*, *|*, *^*, and *%*. The arithmetic operators within *expr* are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

*base*[*expr* [: *size* ] ]

where *expr* evaluates the value of an offset into the packet from a *base* offset which may be *ether*, *ip*, *udp*, *tcp*, or *icmp*. The

size value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

```
ether[0] & 1 = 1
```

is equivalent to `multicast`

```
ether[2:4] = 0xffffffff
```

is equivalent to `broadcast`.

```
ip[ip[0] & 0xf * 4 : 2] = 2049
```

is equivalent to `udp[0:2] = 2049`

```
ip[0] & 0xf > 5
```

selects IP packets with options.

```
ip[6:2] & 0x1fff = 0
```

eliminates IP fragments.

```
udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0
```

finds all packets with UDP checksums.

The `length` primitive may be used to obtain the length of the packet. For instance "`length > 60`" is equivalent to "`greater 60`", and "`ether[length - 1]`" obtains the value of the last byte in a packet.

**and**

Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "`dinky pinky`" is the same as "`dinky AND pinky`".

**or or ,**

Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "`dinky, pinky`" is the same as "`dinky OR pinky`".

**not or !**

Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

**slp**

True if the packet is an SLP packet.

snoop(1M)

**EXAMPLES** | **EXAMPLE 1** Using the snoop Command

Capture all packets and display them as they are received:

```
example# snoop
```

Capture packets with host funky as either the source or destination and display them as they are received:

```
example# snoop funky
```

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

```
example# snoop -o cap funky pinky
example# snoop -i cap -t r | more
```

To look at selected packets in another capture file:

```
example# snoop -i pkts -p 99,108
 99 0.0027 boutique -> sunroof NFS C GETATTR FH=8E6C
100 0.0046 sunroof -> boutique NFS R GETATTR OK
101 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102 0.0102 marmot -> viper NFS C LOOKUP FH=561E screen.r.13.i386
103 0.0072 viper -> marmot NFS R LOOKUP No such file or directory
104 0.0085 bugbomb -> sunroof RLOGIN C PORT=1023 h
105 0.0005 kandinsky -> sparky RSTAT C Get Statistics
106 0.0004 beeblebrox -> sunroof NFS C GETATTR FH=0307
107 0.0021 sparky -> kandinsky RSTAT R
108 0.0073 office -> jeremiah NFS C READ FH=2584 at 40960 for 8192
```

To look at packet 101 in more detail:

```
example# snoop -i pkts -v -p101
ETHER: ----- Ether Header -----
ETHER:
ETHER: Packet 101 arrived at 16:09:53.59
ETHER: Packet size = 210 bytes

```

**EXAMPLE 1** Using the snoop Command (Continued)

```

IP: Protocol = 17 (UDP)
IP: Header checksum = 18DC
IP: Source address = 129.144.40.222, boutique
IP: Destination address = 129.144.40.200, sunroof
IP:
UDP: ----- UDP Header -----
UDP:
UDP: Source port = 1023
UDP: Destination port = 2049 (Sun RPC)
UDP: Length = 176
UDP: Checksum = 0
UDP:
RPC: ----- SUN RPC Header -----
RPC:
RPC: Transaction id = 665905
RPC: Type = 0 (Call)
RPC: RPC version = 2
RPC: Program = 100003 (NFS), version = 2, procedure = 1
RPC: Credentials: Flavor = 1 (Unix), len = 32 bytes
RPC: Time = 06-Mar-90 07:26:58
RPC: Hostname = boutique
RPC: Uid = 0, Gid = 1
RPC: Groups = 1
RPC: Verifier : Flavor = 0 (None), len = 0 bytes
RPC:
NFS: ----- SUN NFS -----
NFS:
NFS: Proc = 11 (Rename)
NFS: File handle = 000016430000000100080000305A1C47
NFS: 597A0000000800002046314AFC450000
NFS: File name = MTra00192
NFS: File handle = 000016430000000100080000305A1C47
NFS: 597A0000000800002046314AFC450000
NFS: File name = .nfs08
NFS:

```

To view just the NFS packets between sunroof and boutique:

```

example# snoop -i pkts rpc nfs and sunroof and boutique
1 0.0000 boutique -> sunroof NFS C GETATTR FH=8E6C
2 0.0046 sunroof -> boutique NFS R GETATTR OK
3 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08

```

To save these packets to a new capture file:

```

example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

```

To view encapsulated packets, there will be an indicator of encapsulation:

```

example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request (1 encap)

```

If -V is used on an encapsulated packet:

## snoop(1M)

### EXAMPLE 1 Using the snoop Command (Continued)

```
example# snoop -V ip-in-ip
sunroof -> boutique ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique IP D=129.144.40.222 S=129.144.40.200 LEN=104, ID=27497
sunroof -> boutique IP D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique ICMP Echo request
```

### EXAMPLE 2 Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: `greater`, `less`, `port`, `rpc`, `nofrag`, and `relop`. The presence of `OR` makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be `OR`'d.

To capture packets between `funky` and `pinky` of type `tcp` or `udp` on port 80:

```
example# snoop funky and pinky and port 80 and tcp or udp
```

Since the primitive `port` cannot be handled by the kernel filter, and there is also an `OR` in the expression, a more efficient way to filter is to move the `OR` to the end of the expression and to use parentheses to enforce the `OR` between `tcp` and `udp`:

```
example# snoop funky and pinky and (tcp or udp) and port 80
```

**EXIT STATUS**

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

**FILES**

|                            |                                                     |
|----------------------------|-----------------------------------------------------|
| <code>/dev/audio</code>    | Symbolic link to the system's primary audio device. |
| <code>/dev/null</code>     | The null file.                                      |
| <code>/etc/hosts</code>    | Host name database.                                 |
| <code>/etc/rpc</code>      | RPC program number data base.                       |
| <code>/etc/services</code> | Internet services and aliases.                      |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `netstat(1M)`, `hosts(4)`, `rpc(4)`, `services(4)`, `attributes(5)`, `audio(7I)`, `bufmod(7M)`, `dlpi(7P)`, `le(7D)`, `pfmod(7M)`, `tun(7M)`

Callaghan, B. and Gilligan, R. *RFC 1761, Snoop Version 2 Packet Capture File Format*. Network Working Group. February 1995.

**WARNINGS**

The processing overhead is much higher for realtime packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the `-o` option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly if the captured packets are interpreted realtime. This processing load further increases if verbose options are used. Since heavy use of `snoop` may deny computing resources to other processes, it should not be used on production servers. Heavy use of `snoop` should be restricted to a dedicated computer.

`snoop` does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

`snoop` may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the `snaplen` (`-s` option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s ethernet, do not set `snaplen` less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s ethernet, `snaplen` should be 250 bytes or more.

`snoop` requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

## soconfig(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | soconfig – configure transport providers for use by sockets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <pre>/sbin/soconfig -f file<br/><br/>/sbin/soconfig family type protocol [path]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>soconfig</code> utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the <code>socket(3SOCKET)</code> call are mapped to the name of a transport provider such as <code>/dev/tcp</code>. This utility can be used to add an additional mapping or remove a previous mapping.</p> <p>The <code>init(1M)</code> utility uses <code>soconfig</code> with the <code>sock2path(4)</code> file during the booting sequence.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-f file</code> Set up the <code>soconfig</code> configuration for each driver according to the information stored in <code>file</code>. A <code>soconfig</code> file consists of lines of at least the first three fields listed below, separated by spaces:</p> <pre>family type protocol path</pre> <p>These fields are described in the OPERANDS section below.</p> <p>An example of <code>file</code> can be found in the EXAMPLES section below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <table><tr><td><i>family</i></td><td>The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</td></tr><tr><td><i>type</i></td><td>The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</td></tr><tr><td><i>protocol</i></td><td>The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code>. An unspecified protocol number is denoted with the value zero.</td></tr><tr><td><i>path</i></td><td>The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.</td></tr></table> | <i>family</i> | The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer. | <i>type</i> | The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer. | <i>protocol</i> | The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code> . An unspecified protocol number is denoted with the value zero. | <i>path</i> | The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed. |
| <i>family</i>      | The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <i>type</i>        | The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <i>protocol</i>    | The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code> . An unspecified protocol number is denoted with the value zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |

If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using <code>soconfig</code></p> <p>The following example sets up <code>/dev/tcp</code> for family <code>AF_INET</code> and type <code>SOCK_STREAM</code>:</p> <pre>example# soconfig 2 2 0 /dev/tcp</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |               |                                                                                                            |             |                                                                                                        |                 |                                                                                                                                                                                                                                                                                       |             |                                                                                                                                                                                                                                                                                        |

**EXAMPLE 1** Using soconfig (Continued)

The following is a sample file used with the `-f` option. Comment lines begin with a number sign (#):

```
Family Type Protocol Path
2 2 2 0 /dev/tcp
2 2 2 6 /dev/tcp

2 1 1 0 /dev/udp
2 1 1 17 /dev/udp

1 2 2 0 /dev/ticotsord
1 1 1 0 /dev/ticlts

2 4 4 0 /dev/rawip
```

**FILES** /etc/sock2path file containing mappings from sockets to transport providers

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

*Network Interface Guide*

## soladdapp(1M)

**NAME** soladdapp – add an application to the Solstice application registry

**SYNOPSIS** `/usr/snadm/bin/soladdapp [-r registry] -n name -i icon -e executable [args]`

**DESCRIPTION** soladdapp adds an application to the Solstice application registry. After it is added, the application is displayed in the Solstice Launcher main window (see `solstice(1M)`).

**OPTIONS**

- `-r registry` Define the full path name of the Solstice registry file.
- `-n name` Define the name of the tool to be registered.
- `-i icon` Define the full path name of the tool icon.
- `-e executable` Define the full path name of the tool.

*args* Specify any arguments to use with the tool.

When executed without options, soladdapp uses `/opt/SUNWadm/etc/.solstice_registry` (the default registry path).

**RETURN VALUES**

- 0 on success
- 1 on failure
- 2 if the registry is locked
- 3 if the entry is a duplicate.

**EXAMPLES**

**EXAMPLE 1** A sample display of the soladdapp command.

The following adds an application called Disk Manager to the Solstice application registry for display in the Solstice Launcher main window.

```
soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
-i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

**FILES** `/opt/SUNWadm/etc/.solstice_registry`  
The default registry path.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsadml       |

**SEE ALSO** `soldelapp(1M)`, `solstice(1M)`, `attributes(5)`

**NOTES** Globally registered applications are used by local and remote users sharing the software in a particular `/opt` directory. They can be added only using soladdapp.

**NAME** soldelapp – remove an application from the Solstice application registry

**SYNOPSIS** `/usr/snadm/bin/soldelapp [-r registry] -n name`

**DESCRIPTION** soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see `solstice(1M)`).

**OPTIONS**

- `-r registry` Define the full path name of the Solstice registry file.
- `-n name` Define the name of the tool to be removed.

When executed without options, soldelapp uses `/opt/SUNWadm/etc/.solstice_registry` (the default registry path).

**RETURN VALUES**

- 0 on success
- 1 on failure
- 2 if the registry is locked
- 3 if *name* is not found in the registry
- 4 if the named registry or default registry is not found

**EXAMPLES**

**EXAMPLE 1** A sample display of the soldelapp command.

The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

```
soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
```

**FILES** `/opt/SUNWadm/etc/.solstice_registry`  
The default registry file.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsdml        |

**SEE ALSO** `soladdapp(1M)`, `solstice(1M)`, `attributes(5)`

**NOTES** Globally registered applications are used by local and remote users sharing the software in a particular `/opt` directory. They can be removed only using soldelapp.

solstice(1M)

**NAME** solstice – access system administration tools with a graphical user interface

**SYNOPSIS** /bin/solstice

**DESCRIPTION** solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

**USAGE** The Solstice Launcher allows you to do the following tasks:

Launch applications

Use the Solstice Launcher to launch system administration tools.

Register applications

Use the Solstice Launcher to add and register applications locally with the launcher.

Remove applications

Use the Solstice Launcher to remove locally registered applications.

Customize application properties

Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

**FILES** /\$HOME/.solstice\_registry  
Local registry information.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsadml       |

**SEE ALSO** soladdapp(1M), soldelapp(1M), attributes(5)

**NOTES** The Solstice Launcher adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the Solstice Launcher. To register global applications for use by local and remote users, use the soladdapp(1M) command. To remove globally registered applications, use the soldelapp(1M) command.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>DESCRIPTION</b> | <p>The sppptun utility is used to configure and query the Solaris PPP tunneling device driver, /dev/sppptun. Currently, only PPP over Ethernet (PPPoE) is supported, so the plumb and unplumb arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the query option lists the plumbed interfaces.</p> <p>The use of sppptun to add interfaces is similar to the use of ifconfig(1M) to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).</p> <p>The proper way to plumb interfaces for PPPoE is to list the interfaces, one per line, in the /etc/ppp/pppoe.if file.</p>                                                                                                                                                                                                                                                                                            |
| <b>USAGE</b>       | <p><b>sppptun plumb</b></p> <p>When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the <i>protocol</i> argument below.</p> <p><b>sppptun plumb</b> <i>protocol device</i></p> <p>This plumbs a new interface into the driver. The <i>protocol</i> parameter is pppoe for the PPP-carrying "Session Stage" connection or pppoed for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The <i>device</i> parameter is the path name of the Ethernet interface to use (use ifconfig(1M) to list available devices). If the path begins with /dev/, then this portion may be omitted.</p> <p><b>sppptun unplumb</b> <i>interface</i></p> <p>This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The <i>interface</i> parameter is the name of the interface as reported when the interface was plumbed.</p> <p><b>sppptun query</b></p> <p>Displays the canonical names of all interfaces plumbed into the /dev/sppptun device driver.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Setting up to Use PPPoE on hme0</p> <p>Plumb the hme0 interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## sppptun(1M)

**EXAMPLE 1** Setting up to Use PPPoE on hme0 (Continued)

```
sppptun plumb pppoe hme0
hme0:pppoe
sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the hme0 interface.

```
sppptun unplumb hme0:pppoe
sppptun unplumb hme0:pppoe
```

**EXAMPLE 2** Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in `sppptun query`
do
 sppptun unplumb $intf
done
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
1 One or more errors occurred.

**FILES** /etc/ppp/pppoe.if list of Ethernet interfaces to be plumbed at boot time  
/usr/sbin/sppptun executable command  
/dev/sppptun Solaris PPP tunneling device driver

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <code>/usr/sbin/spray [-c <i>count</i>] [-d <i>delay</i>] [-l <i>length</i>] [-t <i>nettype</i>] <i>host</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>spray sends a one-way stream of packets to <i>host</i> using RPC, and reports how many were received, as well as the transfer rate. The <i>host</i> argument can be either a name or an Internet address.</p> <p>spray is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. spray can report a large number of packets dropped when the drops were caused by spray sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>OPTIONS</b>     | <p><code>-c <i>count</i></code>           Specify how many packets to send. The default value of <i>count</i> is the number of packets required to make the total stream size 100000 bytes.</p> <p><code>-d <i>delay</i></code>            Specify how many microseconds to pause between sending each packet. The default is 0.</p> <p><code>-l <i>length</i></code>           The <i>length</i> parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of <i>length</i> are possible, and spray rounds up to the nearest possible value. When <i>length</i> is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the <i>length</i> field no longer has a simple correspondence to Ethernet packet size. The default value of <i>length</i> is 86 bytes, the size of the RPC and UDP headers.</p> <p><code>-t <i>nettype</i></code>         Specify class of transports. Defaults to netpath. See rpc(3NSL) for a description of supported classes.</p> |                |                 |              |         |

| <b>NAME</b>        | ssaadm – administration program for SPARCstorage Array and SPARCstorage RSM disk systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <b>ssaadm</b> [-v] [-e] <i>subcommand</i> [ <i>subcommand_option...</i> ]   <i>pathname...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The ssaadm program is an administrative command that manages the SPARCstorage Array and SPARCstorage RSM disk systems (henceforth called SPARCstorage systems). ssaadm performs a variety of control and query tasks depending on the command line arguments and options used.</p> <p>The command line must contain a <i>subcommand</i> (listed under <b>USAGE</b>) and at least one <i>pathname</i>. Commands specific to either a SPARCstorage Array or a SPARCstorage RSM state that fact. It may also contain options and other parameters depending on the subcommand. The subcommand is applied to each of the pathnames on the command line.</p> <p><i>pathname</i> specifies the SPARCstorage system controller or a disk in the SPARCstorage system. The controller name is specified by its physical name, for example,</p> <pre>/devices/. . . /. . . /SUNW,soc@3,0/SUNW,<br/>pln@xxxxxx,xxxxxx:ctlr</pre> <p>or by a name of the form</p> <pre>cN</pre> <p>where <i>N</i> is the logical controller number. ssaadm uses the <i>cN</i> name to find an entry in the <code>/dev/rdisk</code> directory of a disk that is attached to the SPARCstorage system controller. The <code>/dev/rdisk</code> entry is then used to determine the physical name of the SPARCstorage system controller. A disk in the SPARCstorage system is specified by its logical or physical device name, for example,<pre>/dev/rdisk/c1t0d0s2</pre><p>or</p><pre>/devices/. . . /. . . /SUNW,soc@3,0/SUNW,<br/>pln@xxxxxx,xxxxxx/ssd@0,0:c,raw</pre><p>See <a href="#">disks(1M)</a> for more information on logical names for disks and controllers.</p></p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-e                   Expert mode. This is required for the expert mode subcommands listed below.</li><li>-v                   Verbose mode.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Subcommands and their options are described below. Expert mode subcommands are listed separately.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>OPERANDS</b>    | The following operands are supported:<br><br><i>pathname</i> The SPARCstorage system controller or a disk in the SPARCstorage system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Subcommands</b> | <p><code>display [-p] <i>pathname</i> . . .</code><br/>           Display configuration information for the specified units or display performance information for the specified SPARCstorage Array controller. If <i>pathname</i> specifies the controller, the configuration information is displayed for all disks in the SPARCstorage Array. For each drive that has fast write enabled, (FW) are displayed after the drive identification.</p> <p><code>-p</code><br/>           Display performance information for the specified SPARCstorage Array controller. The accumulation of the performance statistics must be enabled using the <code>perf_statistics</code> subcommand before displaying the performance information. If not enabled, all of the I/Os per second are displayed as zeros.</p> <p>The performance display reports the following information:</p> <p><b>BUSY</b><br/>           How busy the controller in the SPARCstorage Array is, expressed as a percentage.</p> <p><b>IOPS</b><br/>           The total I/Os per second for the SPARCstorage Array.</p> <p>entries for each disk<br/>           The total number of I/Os per second.</p> <p><code>download -f <i>filename</i> <i>pathname</i></code><br/> <code>download -w <i>wwn</i> <i>pathname</i></code><br/>           Download an image to the SPARCstorage Array controller.</p> <p><code>-f</code><br/>           Download the prom image specified by <i>filename</i> to the SPARCstorage Array controller FEPROMs. When the download is complete, the SPARCstorage Array must be reset in order to use the downloaded code. Note that the <code>download</code> subcommand modifies the FEPROM on the SPARCstorage Array and should be used <i>with caution</i>.</p> <p><code>-w</code><br/>           Change the SPARCstorage Array controller's World Wide Name. <i>wwn</i> is a 12 digit hex number, leading zeros required. The new SPARCstorage Array controller's image have the least significant 6 bytes of the 8-byte World Wide Name modified to <i>wwn</i>.</p> <p><code>fast_write [-s] -c <i>pathname</i></code><br/> <code>fast_write [-s] -d <i>pathname</i></code></p> |

ssaadm(1M)

`fast_write [-s] -e pathname`

Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* may refer to the SPARCstorage Array controller or to an individual disk.

-c

Enable fast writes for synchronous writes only.

-d

Disable fast writes.

-e

Enable fast writes.

-s

Save the state that is currently being requested so it persists across power-cycles.

`fc_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This subcommand is interactive and expects user confirmation before downloading the fcode. When invoked without the [-f *fcode-file*] option, the current version of the fcode in each FC/S Sbus card is printed. Note that the `fc_s_download` subcommand should be used *only in single-user mode*; otherwise the FC/S card could be reset.

`insert_device pathname`

Guide user through hot insertion of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

`perf_statistics -d pathname`

`perf_statistics -e pathname`

Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be enabled before using the `display -p` subcommand. This subcommand can be issued only to the SPARCstorage Array controller.

-d

Disable the accumulation of performance statistics.

-e

Enable the accumulation of performance statistics.

`purge pathname`

Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.

`release pathname`

Release a reservation held on the specified controllers or disks. When HA (High\_Availability) Software is running on a system, do not use this subcommand to release a disk on an SSA. Doing so could cause problems for the HA software.

`remove_device pathname`

Guide user through hot removal of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

`replace_device pathname`

Guide user through hot replacement of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

`reserve pathname`

Reserve the specified controllers or disks for exclusive use by the issuing host.

When HA (High\_Availability) Software is running on a system, do not use this subcommand to reserve a disk on an SSA. Doing so could cause problems for the HA software.

`set_boot_dev [-y] pathname`

Set the boot-device variable in the PROM to the physical device name specified by *pathname* which can be a block special device or the pathname of the directory on which the boot file system is mounted. This subcommand normally runs interactively and requests confirmation for setting the default boot device in the PROM. The `-y` option can be used to run it in non-interactive mode, in which case no confirmation is requested or required.

`start [-t tray-number] pathname`

Spin up the specified disks. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

`-t`

Spin up all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

`stop [-t tray-number] pathname`

Spin down the specified disks. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

`-t`

Spin down all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

`sync_cache pathname`

Flush all outstanding writes for the specified disk from NVRAM to the media. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

### SCSI Enclosure Services (SES) Subcommands

The SPARCstorage RSM tray is addressed by the using the logical or physical path of the SES device or specifying the controller followed by the tray number if that controller has multiple trays. The controller is addressed by `cN` or the physical path to the SPARCstorage Array's controller.

See `ses(7D)` for more information about environmental sensor cards and associated devices.

These subcommands also work with RSM trays directly attached to wide differential SCSI controllers.

`alarm pathname | controller tray-number`

Display the current state of the audible alarm.

`alarm_on pathname | controller tray-number`

`alarm_off pathname | controller tray-number`

Enable or disable the audible alarm for this enclosure.

`alarm_set pathname | controller tray-number [seconds]`

Set the audible alarm setting to seconds.

`env_display pathname | controller tray-number`

Display the environmental information for the specified unit.

`led pathname`

Display the current state of the led for the specified disk.

`led_on pathname`

`led_off pathname`

Turn on or off the led for this disk.

`power_off pathname | controller tray-number`

Power down this RSM. The RSM will need to be powered back on manually.

This subcommand does not work with RSMs directly attached to wide differential SCSI controllers.

**Expert Mode  
Subcommands**

See NOTES for limitations of these subcommands. Only users that are knowledgeable about the systems they are managing should use the expert mode subcommands.

For the following subcommands that work on a bus if a disk is specified then the bus that disk attached to is used.

`bus_getstate pathname` Get and display the state of the specified bus.

`bus_quiesce pathname` Quiesce the specified bus.

`bus_reset pathname` Reset the specified bus.

`bus_resetall pathname` Reset the specified bus and all devices on that bus.

`bus_unquiesce pathname` Unquiesce the specified bus.

`dev_getstate pathname` Get the state (*online* or *offline*) of the specified device.

`dev_reset pathname` Reset the specified device.

`offline pathname` Turn the specified disk offline.

`online pathname` Turn the specified disk online.

**EXAMPLES** **EXAMPLE 1** Using ssaadm to remove a disk on an SSA

An example of using the expert mode hot plugging subcommands to hot remove a disk on a SSA follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed via its second SCSI bus:

```
example# ssaadm reserve /dev/dsk/c1t8d0s2
```

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# ssaadm -e offline /dev/dsk/c1t8d0s2
example# ssaadm -e bus_quiesce /dev/dsk/c1t8d0s2
```

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then releasing it:

```
example# ssaadm -e bus_unquiesce /dev/dsk/c1t8d0s2
example# ssaadm -e online /dev/dsk/c1t8d0s2
example# ssaadm release /dev/dsk/c1t8d0s2
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
non-zero An error occurred.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWssaop       |

*SPARCstorage Array User's Guide*

**NOTES** Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
ssaadm: can't acquire "PATHNAME": No such file or directory
```

is displayed.

Do not quiesce any bus containing a disk with the root, usr, or swap partitions to avoid possible system deadlock.

## statd(1M)

| <b>NAME</b>        | statd – network status monitor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/lib/nfs/statd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>statd is an intermediate version of the status monitor. It interacts with lockd(1M) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.</p> <p>statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.</p> |                |                 |              |         |
| <b>FILES</b>       | <p><code>/var/statmon/sm</code><br/>lists hosts and network addresses to be contacted after a reboot</p> <p><code>/var/statmon/sm.bak</code><br/>lists hosts and network addresses that could not be contacted after last reboot</p> <p><code>/var/statmon/state</code><br/>includes a number which changes during a reboot</p> <p><code>/usr/include/rpcsvc/sm_inter.x</code><br/>contains the rpcgen source code for the interface services provided by the statd daemon.</p>                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>strace</b> [ <i>mid sid level...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>strace without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see <code>log(7D)</code>). If arguments are provided, they must be in triplets of the form <i>mid, sid, level</i>, where <i>mid</i> is a STREAMS module ID number, <i>sid</i> is a sub-ID number, and <i>level</i> is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token <code>all</code> may be used for any member to indicate no restriction for that attribute.</p> <p>The format of each trace message output is:</p> <pre>&lt;seq&gt; &lt;time&gt; &lt;ticks&gt; &lt;level&gt; &lt;flags&gt; &lt;mid&gt; &lt;sid&gt; &lt;text&gt;</pre> <p>&lt;seq&gt;                    trace sequence number</p> <p>&lt;time&gt;                    time of message in <i>hh:mm:ss</i></p> <p>&lt;ticks&gt;                    time of message in machine ticks since boot</p> <p>&lt;level&gt;                    tracing priority level</p> <p>&lt;flags&gt;                    E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)</p> <p>&lt;mid&gt;                    module ID number of source</p> <p>&lt;sid&gt;                    sub-ID number of source</p> <p>&lt;text&gt;                    formatted text of the trace message</p> <p>Once initiated, <code>strace</code> will continue to execute until terminated by the user.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample output of the <code>strace</code> command:</p> <p>The following example outputs all trace messages from the module or driver whose module ID is 41:</p> <pre>strace 41 all all</pre> <p>The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:</p> <pre>strace 41 0 1 41 1 1 41 2 0</pre> <p>Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

*STREAMS Programming Guide*

- NOTES**
- There is no restriction to the number of `strace` processes opening the STREAMS log driver at a time.
  - The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the `strace` process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running `strace` will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the `strace` process. If trace messages are generated faster than the `strace` process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

| <b>NAME</b>        | strclean – STREAMS error logger cleanup program                                                                                                                                                                                                                                                                         |                |                                                                            |                  |                                                                                            |

| <b>SYNOPSIS</b>    | <b>strclean</b> [-a <i>age</i> ] [-d <i>logdir</i> ]                                                                                                                                                                                                                                                                    |                |                                                                            |                  |                                                                                            |
| <b>DESCRIPTION</b> | strclean is used to clean up the STREAMS error logger directory on a regular basis (for example, by using cron. By default, all files with names matching <code>error.*</code> in <code>/var/adm/streams</code> that have not been modified in the last three days are removed.                                         |                |                                                                            |                  |                                                                                            |
| <b>OPTIONS</b>     | The following options are supported:<br><table> <tr> <td>-a <i>age</i></td> <td>The maximum age in days for a log file can be changed using the -a option.</td> </tr> <tr> <td>-d <i>logdir</i></td> <td>A directory other than <code>/var/adm/streams</code> can be specified using the -d option.</td> </tr> </table> | -a <i>age</i>  | The maximum age in days for a log file can be changed using the -a option. | -d <i>logdir</i> | A directory other than <code>/var/adm/streams</code> can be specified using the -d option. |
| -a <i>age</i>      | The maximum age in days for a log file can be changed using the -a option.                                                                                                                                                                                                                                              |                |                                                                            |                  |                                                                                            |
| -d <i>logdir</i>   | A directory other than <code>/var/adm/streams</code> can be specified using the -d option.                                                                                                                                                                                                                              |                |                                                                            |                  |                                                                                            |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> A sample of using the strclean command.<br>This example has the same result as running strclean with no arguments:<br><pre>example% strclean -d /var/adm/streams -a 3</pre>                                                                                                                            |                |                                                                            |                  |                                                                                            |
| <b>FILES</b>       | <code>/var/adm/streams/error.*</code>                                                                                                                                                                                                                                                                                   |                |                                                                            |                  |                                                                                            |

| <b>NOTES</b>       | strclean is typically run from cron on a daily or weekly basis.                                                                                                                                                                                                                                                         |                |                                                                            |                  |                                                                                            |

strerr(1M)

**NAME** strerr – STREAMS error logger daemon

**SYNOPSIS** **strerr**

**DESCRIPTION** strerr receives error log messages from the STREAMS log driver (see log(7D)) and appends them to a log file. The resultant error log files reside in the directory /var/adm/streams, and are named error.mm-dd, where mm is the month and dd is the day of the messages contained in each log file.

The format of an error log message is:

<seq> <time> <ticks> <flags> <mid> <sid> <text>

<seq> error sequence number

<time> time of message in hh:mm:ss

<ticks> time of message in machine ticks since boot priority level

<flags> T : the message was also sent to a tracing process F : indicates a fatal error N : send mail to the system administrator (hardcoded as root)

<mid> module ID number of source

<sid> sub-ID number of source

<text> formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using mail. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, strerr continues to execute until terminated by the user. It is commonly executed asynchronously.

**FILES** /var/adm/streams/error.mm-dd error log file.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

*STREAMS Programming Guide*

strerr(1M)

**NOTES** | There is no restriction to the number of `strerr` processes opening the STREAMS log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

| <b>NAME</b>        | sttydefs – maintain line settings and hunt sequences for TTY ports                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/sttydefs -a ttylabel [-b] [-f final-flags] [-i initial-flags] [-n nextlabel]  /usr/sbin/sttydefs -l [ttylabel]  /usr/sbin/sttydefs -r ttylabel</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the <code>/etc/ttydefs</code> file.</p> <p>sttydefs with a <code>-a</code> or <code>-r</code> option may be invoked only by the super-user. sttydefs with <code>-l</code> may be invoked by any user on the system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-a ttylabel</code> Add a record to the <code>tttydefs</code> file, using <code>tttylabel</code> as its label. The following describes the effect of the <code>-b</code>, <code>-n</code>, <code>-i</code>, or <code>-f</code> options when used in conjunction with the <code>-a</code> option:</li><li><code>-b</code> Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.</li><li><code>-f final-flags</code> Specify the value to be used in the <code>final-flags</code> field in <code>/etc/ttydefs</code>. <code>final-flags</code> must be in a format recognized by the <code>stty</code> command. <code>final-flags</code> are the <code>termio(7I)</code> settings used by <code>ttymon</code> after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, <code>sttydefs</code> will set <code>final-flags</code> equal to the <code>termio(7I)</code> flags <code>9600</code> and <code>sane</code>.</li><li><code>-i initial-flags</code> Specify the value to be used in the <code>initial-flags</code> field in <code>/etc/ttydefs</code>. <code>initial-flags</code> must be in a format recognized by the <code>stty</code> command. These flags are used by <code>ttymon</code> when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, <code>sttydefs</code> will set <code>initial-flags</code> equal to the <code>termio(7I)</code> flag <code>9600</code>.</li><li><code>-n nextlabel</code> Specify the value to be used in the <code>nextlabel</code> field in <code>/etc/ttydefs</code>. If this option is not specified, <code>sttydefs</code> will set <code>nextlabel</code> equal to <code>tttylabel</code>.</li><li><code>-l[ttylabel]</code> If a <code>tttylabel</code> is specified, <code>sttydefs</code> displays the record from <code>/etc/ttydefs</code> whose TTY label matches the specified <code>tttylabel</code>. If no <code>tttylabel</code> is specified, <code>sttydefs</code></li></ul> |

displays the entire contents of `/etc/ttydefs`.  
`sttydefs` verifies that each entry it displays is correct  
and that the entry's `nextlabel` field references an existing

`-r ttylabel`

Remove any record in the `tttydefs` file that has `ttylabel`  
as its label.

**OUTPUT** If successful, `sttydefs` will exit with a status of 0. `sttydefs -l` will generate the  
requested information and send it to standard output.

**EXAMPLES** **EXAMPLE 1** A sample of `sttydefs` command.

The following command lists all the entries in the `tttydefs` file and prints an error  
message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its  
output:

```
example# sttydefs -l 9600
```

```

9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800

```

```
ttylabel: 9600

initial flags: 9600 hupcl erase ^h

final flags: 9600 sane ixany tab3 hupcl erase ^h

autobaud: no

nextlabel: 4800
```

The following sequence of commands will add the labels 1200, 2400, 4800, and  
9600 and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"

sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"

sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"

sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

**FILES** `/etc/ttydefs`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | su – become super user or another user                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>su</b> [-] [ <i>username</i> [ <i>arg...</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <b>su</b> command allows one to become another user without logging off or to assume a role. The default user <i>name</i> is root (super user).</p> <p>To use <b>su</b>, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, <b>su</b> creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified <i>username</i>. The new shell will be the shell specified in the shell field of <i>username</i>'s password file entry (see <b>passwd(4)</b>). If no shell is specified, <code>/usr/bin/sh</code> is used (see <b>sh(1)</b>). To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.</p> <p>Any additional arguments given on the command line are passed to the new shell. When using programs such as <b>sh</b>, an <i>arg</i> of the form <code>-c string</code> executes <i>string</i> using the shell and an <i>arg</i> of <code>-r</code> gives the user a restricted shell.</p> <p>The following statements are true if the login shell is <code>/usr/bin/sh</code> or an empty string (which defaults to <code>/usr/bin/sh</code>) in the specific user's password file entry. If the first argument to <b>su</b> is a dash (<code>()</code>), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of <code>\$PATH</code>, which is controlled by <code>PATH</code> and <code>SUPATH</code> in <code>/etc/default/su</code>. Additionally, the user's project ID is set if the dash argument is present. See <b>settaskid(2)</b>.</p> <p>All attempts to become another user using <b>su</b> are logged in the log file <code>/var/adm/sulog</code> (see <b>sulog(4)</b>).</p> |
| <b>SECURITY</b>    | <p><b>su</b> uses <b>pam(3PAM)</b> for authentication, account management, and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <b>su</b>. Here is a partial <code>pam.conf</code> file with entries for the <b>su</b> command using the UNIX authentication, account management, and session management module.</p> <pre>su  auth      required    /usr/lib/security/pam_unix.so.1 su  account   required    /usr/lib/security/pam_unix.so.1 su  session    required    /usr/lib/security/pam_unix.so.</pre> <p>If there are no entries for the <b>su</b> service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Becoming User <code>bin</code> While Retaining Your Previously Exported Environment</p> <p>To become user <code>bin</code> while retaining your previously exported environment, execute:</p> <pre>example% su bin</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**EXAMPLE 1** Becoming User `bin` While Retaining Your Previously Exported Environment  
(Continued)

**EXAMPLE 2** Becoming User `bin` and Changing to `bin`'s Login Environment

To become user `bin` but change the environment to what would be expected if `bin` had originally logged in, execute:

```
example% su - bin
```

**EXAMPLE 3** Executing command with user `bin`'s Environment and Permissions

To execute command with the temporary environment and permissions of user `bin`, type:

```
example% su - bin -c "command args"
```

## ENVIRONMENT VARIABLES

Variables with `LD_` prefix are removed for security reasons. Thus, `su bin` will not retain previously exported variables with `LD_` prefix while becoming user `bin`.

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `su` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `su` behaves.

`LC_CTYPE` Determines how `su` handles characters. When `LC_CTYPE` is set to a valid value, `su` can display and handle text and filenames containing valid characters for that locale. `su` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `su` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_MESSAGES` Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

|              |                              |                                                                 |
|--------------|------------------------------|-----------------------------------------------------------------|
| <b>FILES</b> | <code>\$HOME/.profile</code> | user's login commands for <code>sh</code> and <code>ksh</code>  |
|              | <code>/etc/passwd</code>     | system's password file                                          |
|              | <code>/etc/profile</code>    | system-wide <code>sh</code> and <code>ksh</code> login commands |

|           |                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SULOG     | If defined, all attempts to su to another user are logged in the indicated file.                                                                                                                                                                                    |
| CONSOLE   | If defined, all attempts to su to root are logged on the console.                                                                                                                                                                                                   |
| PATH      | Default path. (/usr/bin:)                                                                                                                                                                                                                                           |
| SUPATH    | Default path for a user invoking su to root. (/usr/sbin:/usr/bin)                                                                                                                                                                                                   |
| SYSLOG    | Determines whether the syslog(3C) LOG_AUTH facility should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts. |
| SLEEPTIME | If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.                                                                |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

**NAME** | sulogin – access single-user mode

**SYNOPSIS** | **sulogin**

**DESCRIPTION** | The sulogin utility is automatically invoked by `init` when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke `sulogin`.

The sulogin utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See `consadm(1M)` and `msglog(7D)` for a description of how to configure a serial device to display the single-user login prompt.

**FILES** | `/etc/default/sulogin` | Default value can be set for the following flag:

`PASSREQ` | Determines if login requires a password. Default is `PASSREQ=YES`.

`/etc/default/login` | Default value can be set for the following flag:

`SLEEPTIME` | If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

suninstall(1M)

**NAME** suninstall – install the Solaris environment

**SYNOPSIS** **suninstall**

**DESCRIPTION** suninstall is a forms-based subsystem for installing the operating system.

suninstall only exists on the Solaris CD-ROM and should only be invoked from there. Refer to the installation manual for more details.

suninstall allows installation of the operating system onto any stand-alone system. suninstall loads the software available on the CD-ROM. Refer to the installation manual for disk space requirements.

To abort the installation procedure, use the interrupt character (typically, CTRL-C).

**USAGE** Refer to the installation manual for more information on the various menus and selections.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE        |
|----------------|------------------------|
| Availability   | SUNWcdrom (Solaris CD) |

**SEE ALSO** pkginfo(1), install(1M), pkgadd(1M), attributes(5)

*Solaris 8 Advanced Installation Guide*

**NOTES** It is advisable to exit suninstall through the exit options from the suninstall menus.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>DESCRIPTION</b> | <p>SUNWifb_config configures the Sun Expert3D Graphics Accelerator and some of the X11 window system defaults for the graphics accelerator.</p> <p>The first form of SUNWifb_config shown in the synopsis above stores the specified options in the OWconfig file. These options will be used to initialize the Sun Expert3D device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.</p> <p>The second and third forms of SUNWifb_config, which invoke only the -prconf, -propt, -help, and -res \? options, do not update the OWconfig file. Additionally, for the third form of the command, all other options are ignored.</p> <p>Options may be specified for only one Sun Expert3D device at a time. Specifying options for multiple Sun Expert3D devices requires multiple invocations of SUNWifb_config.</p> <p>Only options specific to the Sun Expert3D device can be specified through SUNWifb_config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line (see the Xsun(1) manual page in the OpenWindows Desktop Reference Manual).</p> |
| <b>OPTIONS</b>     | <p><i>-dev device-filename</i><br/>Specifies the Sun Expert3D special file. The default is /dev/fbs/ifb0.</p> <p><i>-file machine   system</i><br/>Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created.</p> <p><i>-res video-mode</i><br/>Specifies the video mode used to drive the monitor connected to the specified Sun Expert3D device.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## SUNWifb\_config(1M)

The format of these built-in video modes is:

*widthxheightxrate*

where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. The *s* suffix of 960x680x112s and 960x680x108s means that these are stereo video modes. The *i* suffix of 640x480x60i and 768x575x50i designates interlaced video timing. If absent, non-interlaced timing will be used. As a convenience, *-res* also accepts formats with @ (at sign) in front of the refresh rate instead of x. For example: 1280x1024@76. Note that some video-modes supported by the Sun Expert3D device might not be supported by the monitor. The list of video-modes supported by the Sun Expert3D device and the monitor can be obtained by running `SUNWifb_config` with the `-res \?` option (shown in the command synopsis above). A list of all possible video-modes supported on the Sun Expert3D device is shown below:

```
1024x768x60
1024x768x70
1024x768x75
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67
1280x1024x76
1280x1024x85
1280x1024x112s (Stereo)
960x680x112s (Stereo)
960x680x108s (Stereo)
640x480x60
640x480x60i (Interlaced)
768x575x50i (Interlaced)
1440x900x76
1600x1000x66
1600x1000x76
1600x1280x76
1792x1344x75
1920x1080x72
1920x1200x70
```

1920x1200x75

## Symbolic names

For convenience, some of the above video modes have symbolic names defined for them. Instead of the form *width x height x rate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

| Name   | Corresponding Video Mode |
|--------|--------------------------|
| svga   | 1024x768x60              |
| 1152   | 1152x900x76              |
| 1280   | 1280x1024x76             |
| stereo | 960x680x112s             |
| ntsc   | 640x480x60i              |
| pal    | 768x575x50i              |
| none   | (see text above)         |

The `res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of the following might be present.

`now`

If present, not only will the video mode be updated in the `OWconfig` file, but the Sun Expert3D device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

Note that it is inadvisable to use this suboption with `SUNwifb_config` while the configured device is being used (for example, while running the window system); unpredictable results might occur. To run `SUNwifb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen will not change until the window system is exited and reentered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

`noconfirm`

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this,

|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | <p>the default behavior of <code>SUNWifb_config</code> is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The <code>noconfirm</code> option instructs <code>SUNWifb_config</code> to bypass this confirmation and to program the requested video mode anyway. This option is useful when <code>SUNWifb_config</code> is being run from a shell script.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>nocheck</code>                  | <p>If present, the normal error checking based on the monitor sense code (described above) will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the Sun Expert3D device). Use of this option implies <code>noconfirm</code> as well.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>try</code>                      | <p>If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing <code>y</code> within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than <code>y</code> or carriage return is considered a “no” and the previous video mode will be restored and <code>SUNWifb_config</code> will not change the video mode in the <code>OWconfig</code> file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the <code>now</code> suboption (see the warning paragraph under the <code>now</code> suboption).</p>                                                                                                                                     |
| <code>-deflinear true   false</code>  | <p>The Sun Expert3D device possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If <code>true</code>, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the <code>Xsun(1)</code> <code>-defdepth</code> and <code>-defclass</code> options described in the OpenWindows Desktop Reference Manual). If <code>false</code>, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options will be chosen to be the default. This option cannot be used when the <code>-defoverlay</code> option is present, because the Sun Expert3D does not possess a linear overlay visual.</p> |
| <code>-defoverlay true   false</code> | <p>The Sun Expert3D device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the Sun Expert3D visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The converse, however, is not true. Windows created in other visuals will damage overlay windows. If the value of this option is `true`, the overlay visual will be made the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `-defdepth` and `-defclass`, will be chosen as the default visual. See the `Xsun(1)` manual page in the OpenWindows Desktop Reference Manual. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun Expert3D device does not possess a linear overlay visual.

`-linearorder first | last`

If `first`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the Sun Expert3D screen. If `last`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `first`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the Sun Expert3D screen. If `last`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor, and so forth) can be found in the screen visual list.

`-slave enable | disable`

If enabled, the video for this frame buffer will be synced with the video of the display which is connected to it. For applications which support it buffers will also be swapped synchronously.

`-accum enable | disable`

If enabled, frame buffer memory is allocated for accelerated accumulation buffer for windows. If disabled, software accumulation buffering will be done for windows. Accelerated accumulation buffers for pBuffers are always available as memory allows.

`-g gamma-correction_value`

This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma()`. See `XSolarisGetVisualGamma(3)` for a description of that function. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

`-gfile gamma-correction_file`

This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each

## SUNWifb\_config(1M)

line. Each of these values should be in hexadecimal format and separated from each other by at least one space. Also, this file should provide 1024 such triplets. An example of this file is as follows.

```
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
...
...
0x3ff 0x3ff 0x3ff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note that, when gamma correction is being done using a user-specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

### -defaults

Resets all option values to their default values.

### -propt

Prints the current values of all Sun Expert3D options in the OWconfig file specified by the -file option for the device specified by the -dev option. Prints the values of options as they will be in the OWconfig file after the call to SUNWifb\_config completes. This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/ifb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Accum: Disabled (do not allocate an accumulation buffer)
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
 Overlay Visuals are last
OpenGL Visual Expansion: enabled
Gamma Correction Value: 2.22
Gamma Correction Table: Available
```

### -prconf

Prints the Sun Expert3D hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/ifb0 ---
PROM Information: @(#)ifb.fth 1.25 99/10/12 SMI
EDID Data: Available - EDID version 1 revision 1
Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75,
1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s,
640x480x60
Current resolution setting: 1280x1024x76
```

### -help

Prints a list of the SUNWifb\_config command-line options, along with a brief explanation of each.

`-samples 1 | 2 | 4 | 8 | 16`

Requested number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resources exist for the request.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples after you specify the option `-multisample enable` (see below).

`-multisample enable | disable | auto`

If set to `disable`, no multisample is possible. If set to `enable`, multisample is possible but is selected on a per-window basis using a library interface. If set to `auto`, all Sun OpenGL windows are rendered using multisampling.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples if `-multisample` is set to `enable`.

The `xglnfo` utility is shipped with the Sun OpenGL package, `SUNWglrt`. The man page for `xglnfo` is part of another Sun OpenGL package, `SUNWgldoc`.

## DEFAULTS

For a given invocation of `SUNwifb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if a Sun Expert3D option has never been specified via `SUNwifb_config`, a default value is used. The option defaults are as follows:

| Option                     | Default                    |
|----------------------------|----------------------------|
| <code>-dev</code>          | <code>/dev/fbs/ifb0</code> |
| <code>-file</code>         | <code>machine</code>       |
| <code>-res</code>          | <code>none</code>          |
| <code>-deflinear</code>    | <code>false</code>         |
| <code>-defoverlay</code>   | <code>false</code>         |
| <code>-linearorder</code>  | <code>last</code>          |
| <code>-overlayorder</code> | <code>last</code>          |
| <code>-expvis</code>       | <code>enable</code>        |
| <code>-slave</code>        | <code>disable</code>       |
| <code>-accum</code>        | <code>enable</code>        |
| <code>-g</code>            | <code>2.22</code>          |
| <code>-samples</code>      | <code>16</code>            |
| <code>-multisample</code>  | <code>disable</code>       |

The default for the `-res` option of `none` means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This design choice provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX), this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun Expert3D video mode.

## SUNWifb\_config(1M)

### EXAMPLES **EXAMPLE 1** Changing Monitor Resolution

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/lib/fbconfig/SUNWifb_config -res 1280x1024x76
```

**FILES** /dev/fbs/ifb0 device special file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWifbcf       |

**SEE ALSO** `attributes(5)`, `mmap(2)`, `ifb(7D)`, `fbio(7I)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>DESCRIPTION</b> | The swap utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><i>-a swapname</i>      Add the specified swap area. This option can only be used by the super-user. <i>swapname</i> is the name of the swap file: for example, <i>/dev/dsk/c0t0d0s1</i> or a regular file. <i>swaplow</i> is the offset in 512-byte blocks into the file where the swap area should begin. <i>swaplen</i> is the desired length of the swap area in 512-byte blocks. The value of <i>swaplen</i> can not be less than 16. For example, if <i>n</i> blocks are specified, then (<i>n</i>-1) blocks would be the actual swap length. <i>swaplen</i> must be at least one page in length. The size of a page of memory can be determined by using the <code>pagesize</code> command. See <code>pagesize(1)</code>. Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 <code>pagesize</code> bytes. The size of a page of memory is machine dependent.</p> <p><i>swaplow + swaplen</i> must be less than or equal to the size of the swap file. If <i>swaplen</i> is not specified, an area will be added starting at <i>swaplow</i> and extending to the end of the designated file. If neither <i>swaplow</i> nor <i>swaplen</i> are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the <code>/sbin/swapadd</code> script. This script adds all swap areas which have been specified in the <code>/etc/vfstab</code> file; for the syntax of these specifications, see <code>vfstab(4)</code>.</p> <p>To use an NFS or local file-system <i>swapname</i>, you should first create a file using <code>mkfile(1M)</code>. A local file-system swap file can now be added to the running system by just running the <code>swap -a</code> command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:</p> <ol style="list-style-type: none"> <li>1. Add the following line to <code>/etc/dfs/dfstab</code>: <pre> share -F nfs -o rw=<i>clientname</i>, root=<i>clientname</i> <i>path-to-swap-file</i> </pre> </li> </ol> |

## swap(1M)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |                                                                                       |                  |                                                                                             |                     |                                                           |                     |                                                           |                   |                                                                              |

| <code>-d swapname</code> | Delete the specified swap area. This option can only be used by the super-user. <i>swapname</i> is the name of the swap file: for example, <code>/dev/dsk/c0t0d0s1</code> or a regular file. <i>swaplow</i> is the offset in 512-byte blocks into the swap area to be deleted. If <i>swaplow</i> is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.                                                                                                                                                                                                                                                                                                                                                                                                                                 |                        |                                                                                       |                  |                                                                                             |                     |                                                           |                     |                                                           |                   |                                                                              |
| <code>-l</code>          | List the status of all the swap areas. The output has five columns:<br><table><tr><td><code>path</code></td><td>The path name for the swap area.</td></tr><tr><td><code>dev</code></td><td>The major/minor device number in decimal if it is a block special device; zeroes otherwise.</td></tr><tr><td><code>swaplo</code></td><td>The <i>swaplow</i> value for the area in 512-byte blocks.</td></tr><tr><td><code>blocks</code></td><td>The <i>swaplen</i> value for the area in 512-byte blocks.</td></tr><tr><td><code>free</code></td><td>The number of 512-byte blocks in this area that are not currently allocated.</td></tr></table> <p>The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.</p> <p>If <code>swap -l</code> is run while <i>swapname</i> is in the process of being deleted (by <code>swap -d</code>), the string INDEL will appear in a sixth column of the swap stats.</p> | <code>path</code>      | The path name for the swap area.                                                      | <code>dev</code> | The major/minor device number in decimal if it is a block special device; zeroes otherwise. | <code>swaplo</code> | The <i>swaplow</i> value for the area in 512-byte blocks. | <code>blocks</code> | The <i>swaplen</i> value for the area in 512-byte blocks. | <code>free</code> | The number of 512-byte blocks in this area that are not currently allocated. |
| <code>path</code>        | The path name for the swap area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                        |                                                                                       |                  |                                                                                             |                     |                                                           |                     |                                                           |                   |                                                                              |
| <code>dev</code>         | The major/minor device number in decimal if it is a block special device; zeroes otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                        |                                                                                       |                  |                                                                                             |                     |                                                           |                     |                                                           |                   |                                                                              |

swap(1M)

- reserved      The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.
- used          The total amount of swap space in bytes that is either allocated or reserved.
- available     The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the -l option, as well swap space in the form of physical memory.

**USAGE** Only the first 2 Gbyte of a block device larger than 2 Gbyte in size can be used for swap in `swapfs` on a 32-bit operating system. With a 64-bit operating system, a block device larger than 2 Gbyte can be fully utilized for swap up to  $2^{63}-1$  bytes.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `swap`: `LC_CTYPE` and `LC_MESSAGE`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `pagesize(1)`, `mkfile(1M)`, `shareall(1M)`, `getpagesize(3C)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

**WARNINGS** No check is done to determine if a swap area being added overlaps with an existing file system.

## swmtool(1M)

| <b>NAME</b>        | swmtool – install, upgrade, and remove software packages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |           |

| <b>SYNOPSIS</b>    | <b>swmtool</b> [-d <i>directory</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>The <b>swmtool</b> command invokes the <b>admintool(1M)</b> application, which is preselected to add or remove software. Using the <b>swmtool</b> command, you can add software from a product CD or hard disk to an installed system, or you can remove software from an installed system.</p> <p>Once logged in, you may run <b>swmtool</b> to examine the packages on your local system.</p> <p>Membership in the <b>sysadmin</b> group (gid 14) is used to restrict access to administrative tasks. Members of the <b>sysadmin</b> group can use <b>swmtool</b> to add or remove software packages. Non-members have read-only permissions (where applicable).</p> <p>Help is available by using the Help button.</p> |                |                 |              |           |
| <b>OPTIONS</b>     | <p>-d <i>directory</i></p> <p>Specify the directory containing the software to be installed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |           |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample display of using <b>swmtool</b> command.</p> <p>The following example starts the <b>admintool()</b> application and tells it to look for software packages in the local directory <b>/cdrom/cdrom0/s0</b> (the default directory for a CD when running Volume Manager).</p> <pre>example% /usr/sbin/swmtool -d /cdrom/cdrom0/s0</pre>                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |           |

| <b>NAME</b>        | sxconfig – configure contiguous memory for the SX video subsystem                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre> /usr/platform/platform-name/sbin/sxconfig -c /usr/platform/platform-name/sbin/sxconfig -d /usr/platform/ platform-name /sbin/sxconfig [-f   -n] [-l limit] [-s size] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>sxconfig</code> command configures contiguous memory parameters for exclusive use by the SX video system on the Desktop SPARCsystems with graphics option. <code>platform-name</code> can be found using the <code>-i</code> option of <code>uname(1)</code>.</p> <p>After configuring the physically contiguous memory, using the various options described below, the system must be rebooted for the changes to take effect. If this command is being used to configure physically contiguous memory for the first time after the system software has been installed, then the system must be rebooted using the reconfiguration option (<code>-r</code>) of <code>boot(1M)</code>.</p> <p>The amount of memory to be reserved depends upon the type of application. Applications that benefit from the availability of contiguous memory are those that are written to the XGL and XIL graphics and imaging foundation library APIs.</p> <p>The <i>Platform Notes: SPARCstation 10SX System Configuration Guide</i> provides more detailed information regarding how much memory to reserve for various types of graphics and imaging applications.</p> <p><code>sxconfig</code> is supported only on Desktop SPARCsystems with SX graphics option.</p> <p>The interface, output, and command location are uncommitted and subject to change in future releases.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c            Display the current configuration parameters in the driver configuration file. If the system was not rebooted after previously changing the configuration parameters, then the displayed values do not reflect the actual system setup.</li> <li>-d            Restore all configuration parameters to the default values. By default, 0 megabytes of physically contiguous memory are reserved, fragmentation is not allowed, and 32 megabytes of memory are reserved for system use.</li> <li>-f            Allow fragmentation. If no single chunk of memory of at least the requested size is found, allow the request to span multiple chunks. This flag also specifies that less than <code>size</code> megabytes of data may be reserved if there are not enough contiguous chunks available. If this flag is not specified, then the memory reserved must be exactly one chunk of the requested size for the request to succeed.</li> <li>-n            Fragmentation not allowed.</li> </ul>                                                                                                                                                                                                                                                                                |

## sxconfig(1M)

- l *limit* Specify that at least *limit* megabytes of total memory must remain for system use after the contiguous memory has been reserved.
- s *size* Reserve *size* megabytes of contiguous memory for exclusive use by the SX video subsystem.

### EXAMPLES

**EXAMPLE 1** A sample display of using `sxconfig` command.

The following example reserves 16 megabytes of contiguous memory without fragmentation and indicates 32 megabytes of memory should remain for system use after reserving the contiguous memory:

```
example# sxconfig -s 16 -l 32
```

The following example is identical to the one described above except that fragmentation is allowed:

```
example# sxconfig -s 16 -f -l 32
```

The following example reports current configuration parameters in the driver configuration file:

```
example# sxconfig -c
```

This example restores all configuration parameters to the default values:

```
example# sxconfig -d
```

The following example disables fragmentation:

```
example# sxconfig -n
```

### EXIT STATUS

`sxconfig` returns 0 on success, and a positive integer on failure.

- 1 Permission denied. Only root can run this command.
- 2 Configuration file `sx_cmemb.conf` does not exist.
- 3 Illegal option.
- 4 Illegal combination of options.
- 5 Illegal argument for `-s` option. Should be an integer.
- 6 Illegal argument for `-l` option. Should be an integer.

### FILES

`/platform/platform-name/kernel/drv/sx_cmemb` contiguous memory device driver

`/platform/platform-name/kernel/drv/sx_cmemb.conf`  
configuration file for contiguous memory driver

`/etc/init.d/sxcmemb`  
contiguous memory startup script

sync(1M)

**NAME** sync – update the super block

**SYNOPSIS** **sync**

**DESCRIPTION** sync executes the sync system primitive. If the system is to be stopped, sync must be called to insure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See sync(2) for details.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** sync(2), attributes(5)

| <b>DESCRIPTION</b> | <p>The syncinit utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.</p> <p>If run without options, syncinit reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                    |         |       |        |      |     |                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                  |      |     |                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                         |      |     |                                                  |    |                                                 |     |     |                                                        |     |                                                        |
| <b>OPTIONS</b>     | <p>Options to syncinit normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, loop= and loopback= are equivalent.</p> <p>Recognized options are listed in the table below.</p> <table border="1"> <thead> <tr> <th>Keyword</th> <th>Value</th> <th>Effect</th> </tr> </thead> <tbody> <tr> <td rowspan="2">loop</td> <td>yes</td> <td>Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.</td> </tr> <tr> <td>no</td> <td>Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.</td> </tr> <tr> <td rowspan="2">echo</td> <td>yes</td> <td>Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.</td> </tr> <tr> <td>no</td> <td>Disable auto-echo mode.</td> </tr> <tr> <td rowspan="2">nrzi</td> <td>yes</td> <td>Set the port to operate with NRZI data encoding.</td> </tr> <tr> <td>no</td> <td>Set the port to operate with NRZ data encoding.</td> </tr> <tr> <td rowspan="2">txc</td> <td>txc</td> <td>Transmit clock source will be the TxC signal (pin 15).</td> </tr> <tr> <td>rxc</td> <td>Transmit clock source will be the RxC signal (pin 17).</td> </tr> </tbody> </table> |                                                                                                                                                                                                                                                                                                                                                                                                                    | Keyword | Value | Effect | loop | yes | Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud. | no | Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc. | echo | yes | Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test. | no | Disable auto-echo mode. | nrzi | yes | Set the port to operate with NRZI data encoding. | no | Set the port to operate with NRZ data encoding. | txc | txc | Transmit clock source will be the TxC signal (pin 15). | rxc | Transmit clock source will be the RxC signal (pin 17). |
| Keyword            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Effect                                                                                                                                                                                                                                                                                                                                                                                                             |         |       |        |      |     |                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                  |      |     |                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                         |      |     |                                                  |    |                                                 |     |     |                                                        |     |                                                        |

The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.           |         |       |        |      |     |                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                  |      |     |                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                         |      |     |                                                  |    |                                                 |     |     |                                                        |     |                                                        |

The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test. |         |       |        |      |     |                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                  |      |     |                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                         |      |     |                                                  |    |                                                 |     |     |                                                        |     |                                                        |

## syncinit(1M)

|       |                |                                                                 |
|-------|----------------|-----------------------------------------------------------------|
|       | baud           | Transmit clock source will be the internal baud rate generator. |
|       | pll            | Transmit clock source will be the output of the DPLL circuit.   |
| rx    | rx             | Receive clock source will be the RxC signal (pin 17).           |
|       | tx             | Receive clock source will be the TxC signal (pin 15).           |
|       | baud           | Receive clock source will be the internal baud rate generator.  |
|       | pll            | Receive clock source will be the output of the DPLL circuit.    |
| speed | <i>integer</i> | Set the baud rate to <i>integer</i> bits per second.            |

There are also several single-word options that set one or more parameters at a time:

| Keyword  | Equivalent to Options:  |
|----------|-------------------------|
| external | txc=txc rxc=rx loop=no  |
| sender   | txc=baud rxc=rx loop=no |
| internal | txc=pll rxc=pll loop=no |
| stop     | speed=0                 |

### EXAMPLES **EXAMPLE 1** A sample display of syncinit.

The following command sets the first CPU port to loop internally, use internal clocking and operate at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rx
```

syncinit(1M)

**SEE ALSO** syncloop(1M), syncstat(1M), intro(2), ioctl(2), attributes(5), zsh(7D)

**DIAGNOSTICS** *device* missing minor device number

The name *device* does not end in a decimal number that can be used as a minor device number.

bad speed: *arg*

The string *arg* that accompanied the `speed=` option could not be interpreted as a decimal integer.

Bad arg: *arg*

The string *arg* did not make sense as an option.

ioctl failure code = *errno*

An `ioctl(2)` system call failed. The meaning of the value of *errno* may be found in `intro(2)`.

**WARNINGS** `syncinit` should not be used on an active serial link, unless needed to resolve an error condition. It should not be run casually, or if the user is unsure of the consequences of its use.

## syncloop(1M)

| <b>NAME</b>        | syncloop – synchronous serial loopback test program                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/sbin/syncloop [-cdlstv] device</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>syncloop</code> command performs several loopback tests that are useful in exercising the various components of a serial communications link.</p> <p>Before running a test, <code>syncloop</code> opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the <i>device</i> argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.</p> <p>The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, <code>syncloop</code> proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.</p> <p>In the second phase, called the "first-packet" phase, <code>syncloop</code> attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an exhorting message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.</p> <p>The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.</p> <p>After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:</p> <pre>CRC errors   Aborts   Overruns   Underruns   In&lt;-Drops-&gt; Out            0         0         0         0         0         0</pre> <p>This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.</p> |
| <b>OPTIONS</b>     | The options for <code>syncloop</code> are described in the following table:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## syncloop(1M)

| Option | Parameter            | Default       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c     | <i>packet_count</i>  | 100           | Specifies the number of packets to be sent in the multiple-packet phase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -d     | <i>hex_data_byte</i> | <i>random</i> | Specifies that each packet will be filled with bytes with the value of <i>hex_data_byte</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -l     | <i>packet_length</i> | 100           | Specifies the length of each packet in bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -s     | <i>line_speed</i>    | 9600          | Bit rate in bits per second.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -v     |                      |               | Sets verbose mode. If data errors occur, the expected and received data is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -t     | <i>test_type</i>     | <i>none</i>   | A number, from 1 to 4, that specifies which test to perform. The values for <i>test_type</i> are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the <code>syncinit(1M)</code> command. |

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t *test\_type* option, syncloop prompts for it.

### EXAMPLES

**EXAMPLE 1** A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

syncloop(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** syncinit(1M), syncstat(1M), attributes(5), zsh(7D)

**DIAGNOSTICS**

*device* missing minor device number

The name *device* does not end in a decimal number that can be used as a minor device number.

invalid packet length: *nnn*

The packet length was specified to be less than zero or greater than 4096.

poll: nothing to read

poll: nothing to read or write.

The poll(2) system call indicates that there is no input pending and/or that output would be blocked if attempted.

len *xxx* should be *yyy*

The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.

*nnn* packets lost in outbound queueing

*nnn* packets lost in inbound queueing

A discrepancy has been found between the number of packets sent by syncloop and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

**WARNINGS**

To allow its tests to run properly, as well as prevent disturbance of normal operations, syncloop should only be run on a port that is not being used for any other purpose at that time.

| <b>NAME</b>         | syncstat – report driver statistics from a synchronous serial link                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>SYNOPSIS</b>     | <code>/usr/sbin/syncstat [-c] device [interval]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>DESCRIPTION</b>  | <p>The <code>syncstat</code> command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.</p> <p>Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.</p> <p>The <i>device</i> argument is the name of the serial device as it appears in the <code>/dev</code> directory. For example, <code>zsh0</code> specifies the first on-board serial device.</p> <p>The following is a breakdown of <code>syncstat</code> output:</p> <hr/> <table border="0"> <tr> <td style="padding-right: 20px;"><code>speed</code></td> <td>The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.</td> </tr> <tr> <td><code>ipkts</code></td> <td>The total number of input packets.</td> </tr> <tr> <td><code>opkts</code></td> <td>The total number of output packets.</td> </tr> <tr> <td><code>undrun</code></td> <td>The number of transmitter underrun errors.</td> </tr> <tr> <td><code>ovrrun</code></td> <td>The number of receiver overrun errors.</td> </tr> <tr> <td><code>abort</code></td> <td>The number of aborted received frames.</td> </tr> <tr> <td><code>crc</code></td> <td>The number of received frames with CRC errors.</td> </tr> <tr> <td><code>isize</code></td> <td>The average size (in bytes) of input packets.</td> </tr> <tr> <td><code>osize</code></td> <td>The average size (in bytes) of output packets.</td> </tr> </table> <hr/> | <code>speed</code> | The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem. | <code>ipkts</code> | The total number of input packets. | <code>opkts</code> | The total number of output packets. | <code>undrun</code> | The number of transmitter underrun errors. | <code>ovrrun</code> | The number of receiver overrun errors. | <code>abort</code> | The number of aborted received frames. | <code>crc</code> | The number of received frames with CRC errors. | <code>isize</code> | The average size (in bytes) of input packets. | <code>osize</code> | The average size (in bytes) of output packets. |
| <code>speed</code>  | The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |

| <code>osize</code>  | The average size (in bytes) of output packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |
| <b>OPTIONS</b>      | <p>The following options are supported:</p> <p><code>-c</code> Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.</p> <p><i>interval</i> <code>syncstat</code> samples the statistics every <i>interval</i> seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                    |                                                                                                                                                                                         |                    |                                    |                    |                                     |                     |                                            |                     |                                        |                    |                                        |                  |                                                |                    |                                               |                    |                                                |

## syncstat(1M)

### EXAMPLES

#### EXAMPLE 1 Sample Output from the syncstat Command

```
example# syncstat zsh0
speed ipkts opkts undrun ovrrun abort crc isize osize
9600 15716 17121 0 0 1 3 98 89
```

```
example# syncstat -c zsh0
speed ipkts opkts undrun ovrrun abort crc isize osize
9600 0 0 0 0 0 0 0 0
```

In the following sample output a new line of output is generated every five seconds:

```
example# syncstat zsh0 5
ipkts opkts undrun ovrrun abort crc iutil outil
12 10 0 0 0 0 5% 4%
22 60 0 0 0 0 3% 90%
36 14 0 0 0 1 51% 2%
```

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

### SEE ALSO

`syncinit(1M)`, `syncloop(1M)`, `attributes(5)`, `zsh(7D)`

### DIAGNOSTICS

`bad interval: arg`

The argument *arg* is expected to be an interval and could not be understood.

`device missing minor device number`

The name *device* does not end in a decimal number that can be used as a minor device number.

`baud rate not set`

The *interval* option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

### WARNINGS

Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the

syncstat(1M)

modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

| <b>SYNOPSIS</b>    | <pre><b>/usr/sbin/sysdef</b> [-n <i>namelist</i>]<br/><b>/usr/sbin/sysdef</b> [-h] [-d] [-D]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>sysdef</code> utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.</p> <p>It generates the output by analyzing the named bootable operating system file (<i>namelist</i>) and extracting the configuration information from it.</p> <p>The default system <i>namelist</i> is <code>/dev/kmem</code>.</p>                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p><code>-n <i>namelist</i></code> Specifies a <i>namelist</i> other than the default (<code>/dev/kmem</code>). The <i>namelist</i> specified must be a valid bootable operating system.</p> <p><code>-h</code> Prints the identifier of the current host in hexadecimal. This numeric value is unique across all Sun hosts.</p> <p><code>-d</code> The output includes the configuration of system peripherals formatted as a device tree.</p> <p><code>-D</code> For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.</p>                                                                                                                                                                                                                                                      |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Sample output format</p> <p>The following example displays the format of the <code>sysdef -d</code> output:</p> <pre>example% <b>sysdef</b> -d<br/>Node 'Sun 4/60', unit #0 (no driver)<br/>  Node 'options', unit #0 (no driver)<br/>  Node 'zs', unit #0<br/>  Node 'zs', unit #1<br/>  Node 'fd', unit #0<br/>  Node 'audio', unit #0<br/>  Node 'sbus', unit #0<br/>    Node 'dma', unit #0<br/>    Node 'esp', unit #0<br/>    Node 'st', unit #1 (no driver)<br/>    Node 'st', unit #0<br/>    Node 'sd', unit #2<br/>    Node 'sd', unit #1<br/>    Node 'sd', unit #0<br/>    Node 'le', unit #0<br/>    Node 'bwtwo', unit #0<br/>  Node 'auxiliary-io', unit #0<br/>  Node 'interrupt-enable', unit #0<br/>  Node 'memory-error', unit #0<br/>  Node 'counter-timer', unit #0<br/>  Node 'eeprom', unit #0</pre> |

syseventconfd(1M)

**NAME** syseventconfd – kernel system event command invocation daemon

**SYNOPSIS** `/usr/lib/sysevent/syseventconfd [-r rootdir]`

**DESCRIPTION** `syseventconfd` is the user-level daemon that invokes user-level commands in response to kernel system events received from `syseventd(1M)`.

**OPTIONS** The following options are supported:

`-r rootdir` Cause `syseventconfd` to use an alternate root path when creating its door. The root path must match the root path used to invoke `syseventd`.

**FILES**

- `/etc/init.d/devfsadm`  
daemon start and stop script
- `/etc/rcS.d/S50devfsadm`  
link to `init.d` script
- `/etc/rc0.d/K83devfsadm`  
link to `init.d` script
- `/etc/sysevent/syseventconfd_event_service`  
`syseventconfd` event service door file
- `/usr/lib/sysevent/modules/sysevent_conf_mod.so`  
`syseventd` loadable module (SLM) managing `sysevent.conf` files

| <b>NAME</b>        | syseventd – kernel system event notification daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <code>/usr/lib/sysevent/syseventd [-d <i>debug_level</i>] [-r <i>rootdir</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>syseventd is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to propagate the event to all interested end event subscribers.</p> <p>Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt.</p> <p>Upon successful delivery of the event buffer to all interested event subscribers, syseventd frees the event buffer from the kernel event queue.</p>                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-d <i>debug_level</i></code>      Enable debug mode. Messages are printed to the invoking user's terminal.</p> <p><code>-r <i>rootdir</i></code>            Cause syseventd to use an alternate root path when creating its door and lock files. Modules continue to be loaded from the standard module directories.</p>                                                                                                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0                        Successful completion.</p> <p>non-zero                An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>SYNOPSIS</b>    | <b>sysidconfig</b> [-lv] [-a <i>application</i> ] [-b <i>basedir</i> ] [-r <i>application</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>Invoked without any options, the <code>sysidconfig</code> program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, <code>-c</code>. This flag will cause the system configuration application to perform its configuration function. Without options, <code>sysidconfig</code> should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot.</p> <p>All applications on the list will be executed, if possible. All activity taken by the <code>sysidconfig</code> program is logged in the <code>sysidconfig</code> log file, <code>/var/log/sysidconfig.log</code>. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time.</p> <p>Executed with the <code>-l</code>, <code>-a</code>, or <code>-r</code> options, the <code>sysidconfig</code> program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running <code>sysidconfig</code> with options is the only way to view or manipulate the list. Only the super-user can execute the <code>sysidconfig</code> program with options.</p> <p>The <code>-b</code> and <code>-v</code> options change the behavior of <code>sysidconfig</code>, and can be used with or without the list manipulation options discussed above. The <code>-b basedir</code> option is used to specify a reference root directory other than the default, <code>/</code>. The <code>-v</code> option duplicates the log file output on <code>stdout</code>.</p> <p>By default, no SPARC based applications exist on this list. However, the IA based systems are delivered with one application, <code>kdmconfig(1M)</code>, on the list. <code>kdmconfig</code> is not delivered on SPARC based systems.</p> <p>This application is an extension of the <code>sysidtool(1M)</code> suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via <code>sysidconfig -a</code>.</p> <p>This program is referenced, but not fully described, in the <code>sysidtool(1M)</code> manual page.</p> |
| <b>OPTIONS</b>     | <p>The valid options are:</p> <p><code>-a <i>application</i></code>      Add the named application to the list of defined applications. When next invoked without arguments, <code>sysidconfig</code> will run</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## sysidconfig(1M)

- this newly added application after all previously defined applications. *application* must be a fully qualified path name that is not currently on the list of applications to execute.
- b *basedir*** Specify an alternate base directory (/ is defined as the default base directory if no other is specified). The specified directory is used as the *root* directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in */var/log*, relative to the specified *basedir*. In the log file, the *basedir* is not noted. This means, for example, that if the super-user on a diskless client's server executes:
- ```
sysidconfig -b /export/root/client -a /sbin/someapp
```
- then the diskless client *client* would have */sbin/someapp* executed upon reconfigure reboot. The diskless client's log file would note that */sbin/someapp* was added, not */export/root/client/sbin/someapp*.
- l** List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.
- r *application*** Remove the named application from the list of defined applications. *application* must be a fully qualified path name and it must be on the existing list of applications to execute.
- v** Verbose mode. This option echoes all information sent to the log file to *stdout*. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

RETURN VALUES The *sysidconfig* program will return 0 if it completes successfully.

When executed with the *-r* or *-a* options, error conditions or warnings will be reported on *stderr*. If the requested action completes successfully, an exit code of 0 will be returned.

ERRORS

EPERM	The program was executed by a user other than the super-user.
EINVAL	Option <i>-l</i> , <i>-a</i> , or <i>-r</i> was passed and the action could not be completed successfully.

FILES */var/log/sysidconfig.log* *sysidconfig* log file

IA Only	kdmconfig(1M)
DIAGNOSTICS	When run without options, a log of the <code>sysidconfig</code> program's activity can be found in <code>/var/log/sysidconfig.log</code> . This file contains a timestamp log of each program executed, its resulting <code>stderr</code> output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.

sysidtool(1M)

NAME	sysidtool, sysidnet, sysidns, sysidsys, sysidroot, sysidpm – system configuration												
SYNOPSIS	<code>/usr/sbin/sysidnet</code> <code>/usr/sbin/sysidns</code> <code>/usr/sbin/sysidsys</code> <code>/usr/sbin/sysidroot</code> <code>/usr/sbin/sysidpm</code>												
DESCRIPTION	<p>sysidtool is a suite of five programs that configure a new system, or one that has been unconfigured with <code>sys-unconfig(1M)</code>. The <code>sysidtool</code> programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured.</p> <p>These programs have no effect except at such times, and should never be run manually.</p> <p>The <code>sysidtool</code> programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. The following list shows the available commands and the information for which each of the commands lists.</p> <table><tr><td><code>sysidnet</code>: network configuration</td><td>Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.</td></tr><tr><td><code>sysidns</code>: Name Service configuration</td><td>Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network). Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)</td></tr><tr><td><code>sysidsys</code>: miscellaneous system configuration</td><td>Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.</td></tr><tr><td><code>sysidroot</code>: control superuser information</td><td>Machine's root password.</td></tr><tr><td><code>sysidpm</code>: Power Management configuration</td><td>Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.</td></tr><tr><td><code>sysidconfig</code>: host or platform-specific configuration</td><td>This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. <code>Seesysidconfig(1M)</code>.</td></tr></table> <p>The <code>sysidtool</code> programs attempt to obtain system configuration information from various name service databases (for example, NIS) or from the <code>sysidcfg(4)</code> file, and</p>	<code>sysidnet</code> : network configuration	Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.	<code>sysidns</code> : Name Service configuration	Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network). Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)	<code>sysidsys</code> : miscellaneous system configuration	Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.	<code>sysidroot</code> : control superuser information	Machine's root password.	<code>sysidpm</code> : Power Management configuration	Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.	<code>sysidconfig</code> : host or platform-specific configuration	This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. <code>Seesysidconfig(1M)</code> .
<code>sysidnet</code> : network configuration	Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.												
<code>sysidns</code> : Name Service configuration	Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network). Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)												
<code>sysidsys</code> : miscellaneous system configuration	Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.												
<code>sysidroot</code> : control superuser information	Machine's root password.												
<code>sysidpm</code> : Power Management configuration	Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.												
<code>sysidconfig</code> : host or platform-specific configuration	This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. <code>Seesysidconfig(1M)</code> .												

you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the `sysidcfg(4)` file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See *Solaris 8 Advanced Installation Guide* for more details about how to preconfigure the system configuration information.

The machine's configuration information is set up in its `/etc` and `/var` files.

Solaris 8 Advanced Installation Guide

NOTES | If a system has more than one network interface, you can use `sysidtool` to configure only the primary interface on the system. All other interfaces on the system must be configured manually.

You cannot use the name service databases or the `sysidcfg(4)` file to suppress the Power Management configuration prompt; however, you can suppress it by creating either the `/autoshtutdown` or `/noautoshtutdown` file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The `/autoshtutdown` or `/noautoshtutdown` files are removed by `sysidpm` before it exits.

NAME	syslogd – log system messages
SYNOPSIS	<code>/usr/sbin/syslogd [-d] [-f <i>configfile</i>] [-m <i>markinterval</i>] [-p <i>path</i>] [-t]</code>
DESCRIPTION	<p>syslogd reads and forwards system messages to the appropriate log files and/or users, depending upon the priority of a message and the system facility from which it originates. The configuration file <code>/etc/syslog.conf</code> (see <code>syslog.conf(4)</code>) controls where messages are forwarded. syslogd logs a mark (timestamp) message every <i>markinterval</i> minutes (default 20) at priority LOG_INFO to the facility whose name is given as mark in the <code>syslog.conf</code> file.</p> <p>A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <code><sys/syslog.h></code>.</p> <p>syslogd reads from the STREAMS log driver, <code>/dev/log</code>, and from any transport provider specified in <code>/etc/netconfig</code>, <code>/etc/net/transport/hosts</code>, and <code>/etc/net/transport/services</code>.</p> <p>syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see <code>signal(3HEAD)</code>), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal.</p> <p>As it starts up, syslogd creates the file <code>/etc/syslog.pid</code>, if possible, containing its process identifier (PID).</p> <p>If message ID generation is enabled (see <code>log(7D)</code>), each message will be preceded by an identifier in the following format: <code>[ID <i>msgid facility . priority</i>]</code>. <i>msgid</i> is the message's numeric identifier described in <code>msgid(1M)</code>. <i>facility</i> and <i>priority</i> are described in <code>syslog.conf(4)</code>. <code>[ID 123456 kern.notice]</code> is an example of an identifier when message ID generation is enabled.</p> <p>If the message originated in a loadable kernel module or driver, the kernel module's name (for example, <code>ufs</code>) will be displayed instead of <code>unix</code>. See <code>EXAMPLES</code> for sample output from syslogd with and without message ID generation enabled.</p> <p>In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See <code>EXAMPLES</code>.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-d</code> Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should <i>not</i> be used in the system start-up scripts, as this will cause the system to hang at the point where syslogd is started.</p> <p><code>-f <i>configfile</i></code> Specify an alternate configuration file.</p>

syslogd(1M)

<code>-m <i>markinterval</i></code>	Specify an interval, in minutes, between mark messages.
<code>-p <i>path</i></code>	Specify an alternative log device name. The default is <code>/dev/log</code> .
<code>-t</code>	Disable the <code>syslogd</code> UPD port to turn off logging of remote messages.

EXAMPLES **EXAMPLE 1** syslogd output without message ID generation enabled

The following example shows the output from `syslogd` when message ID generation is *not* enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

EXAMPLE 2 syslogd output with ID generation enabled when writing to log file `/var/adm/messages`

The following example shows the output from `syslogd` when message ID generation is enabled. Note that the message ID is displayed when writing to log file `/var/adm/messages`.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice] alloc /: file system full
```

EXAMPLE 3 syslogd output with ID generation enabled when writing to the console

The following example shows the output from `syslogd` when message ID generation is enabled when writing to the console. Note that even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```

FILES	<code>/etc/syslog.conf</code>	configuration file
	<code>/etc/syslog.pid</code>	process ID
	<code>/dev/log</code>	STREAMS log driver
	<code>/etc/netconfig</code>	specifies the transport providers available on the system
	<code>/etc/net/transport/hosts</code>	network hosts for each transport
	<code>/etc/net/transport/services</code>	network services for each transport

NOTES The mark message is a system time stamp, and so it is only defined for the system on which syslogd is running. It can not be forwarded to other systems.

sys-unconfig(1M)

NAME	sys-unconfig – undo a system’s configuration
SYNOPSIS	<code>/usr/sbin/sys-unconfig</code>
DESCRIPTION	<p>The <code>sys-unconfig</code> command is used to restore a system’s configuration to an “as-manufactured” state, ready to be reconfigured again. The system’s configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the <code>sysidnet(1M)</code>, <code>sysidns(1M)</code>, and <code>sysidsys(1M)</code> programs run at boot. See <code>sysidtool(1M)</code>.</p> <p><code>sys-unconfig</code> does the following:</p> <ul style="list-style-type: none">■ Saves current <code>/etc/inet/hosts</code> file information in <code>/etc/inet/hosts.saved</code>.■ If the current <code>/etc/vfstab</code> file contains NFS mount entries, saves the <code>/etc/vfstab</code> file to <code>/etc/vfstab.orig</code>.■ Restores the default <code>/etc/inet/hosts</code> file.■ Removes the default hostname in <code>/etc/hostname.interface</code> files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command <code>ifconfig-a</code>. The <code>/etc/hostname.interface</code> files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (lo0), will be removed.■ Removes the default domainname in <code>/etc/defaultdomain</code>.■ Restores the timezone to PST8PDT in <code>/etc/TIMEZONE</code>.■ Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured.■ Removes the entries for this host in <code>/etc/net/*/hosts</code>.■ Removes the file <code>/etc/inet/netmasks</code>.■ Removes the file <code>/etc/defaultrouter</code>.■ Removes the password set for root in <code>/etc/shadow</code>.■ Removes the file <code>/etc/.rootkey</code>.■ Executes all system configuration applications. These applications are defined by prior executions of a <code>sysidconfig -a application</code>. (See <code>sysidconfig(1M)</code>). When <code>sys-unconfig</code> is run, all system configuration applications are passed one argument, <code>-u</code>.■ Removes the file <code>/etc/resolv.conf</code>.■ Disables LDAP by removing <code>/var/ldap/ldap_client_cache</code>, <code>/var/ldap/ldap_client_file</code>, <code>/var/ldap/ldap_client_cred</code>, and <code>/var/ldap/cachemgr.log</code>. <p>When <code>sys-unconfig</code> is finished, it performs a system shutdown. <code>sys-unconfig</code> is a potentially dangerous utility and can only be run by the super user.</p>
FILES	<code>/etc/default/init</code> process control initialization

```

/etc/defaultdomain
/etc/defaultrouter
/etc/hostname.interface
/etc/inet/hosts          host name database
/etc/inet/netmasks      network mask database
/etc/net/*/hosts
/etc/nodename
/etc/.rootkey           super-user's secret key
/etc/shadow             shadow password file
/etc/vfstab            virtual file system table
/var/nis/NIS_COLD_START
/var/yp/binding/*/ypservers

tapes(1M)

NAME	tapes – creates /dev entries for tape drives attached to the system
SYNOPSIS	<code>/usr/sbin/tapes [-r rootdir]</code>
DESCRIPTION	<p>devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of tapes.</p> <p>tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:</p> <ol style="list-style-type: none">1. The /dev/rmt directory is searched for a /dev/rmt/n entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive. <p>tapes does not remove links to non-existent devices; these must be removed by hand.</p> <p>tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed. When invoking tapes(1M) manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.</p>
Notice to Driver Writers	<p>tapes(1M) considers all devices with the node type DDI_NT_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [l,m,h,c,u][b][n].</p> <p>The first character set is used to specify the tape density of the device, and are named low (l), medium (m), high (h), compressed (c), and ultra (u). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where l means 800 BPI, m means 1600 BPI, and h means 6250 BPI, whereas 4mm DAT tapes defines l as standard format, and m, h, c and u as compressed format. Drivers may choose to implement any or all of these format types.</p> <p>During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. b instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.</p> <p>n or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).</p>

The minor number for tape devices should be created by encoding the device's instance number using the tape macro `MTMINOR` and ORing in the proper combination of density, BSD behavior, and no-rewind flags. See `mtio(7I)`.

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string `DDI_NT_TAPE` when calling `ddi_create_minor_node(9F)`.

OPTIONS `-r rootdir` Causes tapes to presume that the `/dev/rmt` directory tree is found under `rootdir`, not directly under `/`.

ERRORS If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

EXAMPLES **EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's `attach()` Function

This example demonstrates creating tape device nodes from within the `xktape` driver's `attach(9E)` function.

```
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int  minor_mode;
};
/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
    {"", 0}, /* default tape */
    {"1", MT_DENSITY1},
    {"1b", MT_DENSITY1 | MT_BSD},
    {"1bn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
    {"m", MT_DENSITY2},
    {"mb", MT_DENSITY2 | MT_BSD},
    {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
    {"h", MT_DENSITY3},
    {"hb", MT_DENSITY3 | MT_BSD},
    {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
    {"c", MT_DENSITY4},
    {"cb", MT_DENSITY4 | MT_BSD},
    {"cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND},
    {NULL, 0},
};

int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance;
    struct tape_minor_info *mdp;
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
```

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function
(Continued)

```

    for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
        ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
            (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
    }
}

```

Installing the `xktape` driver on a SPARCstation 20, with the driver controlling a SCSI tape (target 4 attached to an `esp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```

# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/espdma@f,400000/esp@f,800000/
crw-rw-rw-  1 root sys  33,136 Aug 29 00:02  xktape@4,0:

taskstat(1M)

NAME taskstat – prints ASET tasks status

SYNOPSIS `/usr/aset/util/taskstat [-d aset_dir]`

DESCRIPTION taskstat is located in the `/usr/aset/util` directory. `/usr/aset` is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the `aset -d` command or the `ASETDIR` environment variable. See `aset(1M)`. Because `aset` dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. `taskstat` prints the status of the tasks, listing those that are completed and those that are still executing.

The ASET reports, which are located in the `/usr/aset/reports` directory (see the `-d` option), are not complete until all the tasks finish executing.

OPTIONS `-d aset_dir` Specify the working directory for ASET. By default, this directory is `/usr/aset`. With this option, the `reports` directory will be located under `aset_dir`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	tcxconfig – configure the default linearity of the 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer (TCX)				
SYNOPSIS	<code>/usr/sbin/tcxconfig</code> [<code>linear</code> <code>nonlinear</code>]				
DESCRIPTION	<p>The <code>tcxconfig</code> script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run <code>tcxconfig</code> with an argument that specifies the setting you want.</p> <p>OpenWindows should not be running when you execute the <code>tcxconfig</code> script with an option. Start OpenWindows after <code>tcxconfig</code> has set the linearity you desire.</p>				
OPTIONS	<p>If you specify no option, <code>tcxconfig</code> displays the current default setting.</p> <p>You must become superuser before you can execute <code>tcxconfig</code> with one of the following options.</p> <p><code>linear</code> Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.</p> <p><code>nonlinear</code> Set nonlinear visual to be the default 24-bit TrueColor Visual.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 success</p> <p>1 an error has occurred.</p>

tic(1M)

NAME tic – terminfo compiler

SYNOPSIS `tic [-v [n]] [-c] file`

DESCRIPTION The command `tic` translates a `terminfo` file from the source format into the compiled format. The results are placed in the directory `/usr/share/lib/terminfo`. The compiled format is necessary for use with the library routines in `curses(3CURSES)`.

If the environment variable `TERMINFO` is set, the compiled results are placed there instead of `/usr/share/lib/terminfo`.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

OPTIONS

- `-vn` Specify that (verbose) output be written to standard error trace information showing `tic`'s progress. The optional integer `n` is a number from 1 to 10, indicating the desired level of detail of information. If `n` is omitted, the default level is 1. If `n` is specified and greater than 1, the level of detail is increased.
- `-c` Specifies to check only `file` for errors. Errors in `use=` links are not detected.
- `file` Contains one or more `terminfo` terminal descriptions in source format [see `terminfo(4)`]. Each description in the file describes the capabilities of a particular terminal. When a `use=entry-name` field is discovered in a terminal entry currently being compiled, `tic` reads in the binary from `/usr/share/lib/terminfo` to complete the entry. (Entries created from `file` will be used first. If the environment variable `TERMINFO` is set, that directory is searched instead of `/usr/share/lib/terminfo`.) `tic` duplicates the capabilities in `entry-name` for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

FILES `/usr/share/lib/terminfo/?/*` compiled terminal description database

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `captainfo(1M)`, `infocmp(1M)`, `curses(3CURSES)`, `terminfo(4)`, `attributes(5)`

NOTES When an entry, for example, `entry_name_1`, contains a `use=entry_name_2` field, any canceled capabilities in `entry_name_2` must also appear in `entry_name_1` before `use=` for these capabilities to be canceled in `entry_name_1`.

NAME	tracert – print the route packets take to network host
SYNOPSIS	<pre> tracert [-adFIlnSvx] [-A <i>addr_family</i>] [-c <i>traffic_class</i>] [-f <i>first_hop</i>] [-g <i>gateway</i> [-g <i>gateway...</i>] -r] [-i <i>iface</i>] [-L <i>flow_label</i>] [-m <i>max_hop</i>] [-P <i>pause_sec</i>] [-p <i>port</i>] [-Q <i>max_timeout</i>] [-q <i>nqueries</i>] [-s <i>src_addr</i>] [-t <i>tos</i>] [-w <i>wait_time</i>] host [<i>packetlen</i>] </pre>
DESCRIPTION	<p>The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility <code>tracert</code> traces the route that an IP packet follows to another internet host.</p> <p>The <code>tracert</code> utility utilizes the both the IPv4 and IPv6 protocols. Use the <code>-A</code> option to override the default behavior. <code>tracert</code> uses the IPv4 protocol <i>tll</i> (time to live) field or the IPv6 field <i>hop limit</i>. It attempts to elicit an ICMP or ICMP6 <code>TIME_EXCEEDED</code> response from each <i>gateway</i> along the path, and a <code>PORT_UNREACHABLE</code>(or <code>ECHO_REPLY</code> if <code>-I</code> is used) response from the destination host. It starts by sending probes with a <i>tll</i> or <i>hop limit</i> of 1 and increases by 1 until it either gets to the host, or it hits the maximum <i>max_hop</i>. The default maximum <i>max_hop</i> is 30 hops, but this can be set by the <code>-m</code> option.</p> <p>Three probes are sent at each <i>tll</i> (<i>hop limit</i>) setting, and a line is printed showing the <i>tll</i> (<i>hop limit</i>), the hostname and the address of the gateway, and the <i>rtt</i> (round trip time) of each probe. The number of probes may be specifically set using the <code>-q</code> option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, a "*" is printed for that probe. The <code>-w</code> option may be used to set the timeout interval. Other possible annotations that may appear after the time are:</p> <ul style="list-style-type: none"> ! <i>tll</i> (<i>hop limit</i>) value in the received packet is <= 1. !H host unreachable. !X communication administratively prohibited. <!N> ICMP (ICMP6) unreachable code N. <p>The following annotations appear only for IPv4:</p> <ul style="list-style-type: none"> !F fragmentation needed. This should never occur. If this is seen, the associated gateway is broken. !N network unreachable. !P protocol unreachable. !S source route failed. This should never occur. If this is seen, the associated gateway is broken. !T unreachable for the specified <i>tos</i> (type-of-service). !U source host isolated or precedence problem. <p>The following annotations appear only for IPv6:</p>

traceroute(1M)

- !A host unreachable for a reason other than lack of an entry in the routing table.
- !B packet too big.
- !E destination is not a neighbor.
- !R unrecognized next header.

If almost all the probes result in some kind of unreachable code, then `traceroute` gives up and exits.

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the `-p` option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All integer arguments to `traceroute` can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as 256 or 0x100.

OPTIONS

- `-A addr_family` Specify the address family of the target host. *addr_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `traceroute` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `traceroute` will use the IPv4 address associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `traceroute` will use the IPv6 address that is associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit.
- `-a` Probe all of the addresses of a multi-homed destination. The output looks like `traceroute` has been run once for each IP address of the destination. If

	<p>this option is used together with <code>-A</code>, <code>tracertool</code> probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a <code>SIGINT</code>, or exit <code>tracertool</code> by sending a <code>SIGQUIT</code> signal. See <code>signal(3HEAD)</code></p>
<code>-c traffic_class</code>	<p>Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of <code>traffic_class</code> set in the probe packet. This option is valid only on IPv6.</p>
<code>-d</code>	<p>Set the <code>SO_DEBUG</code> socket option.</p>
<code>-F</code>	<p>Set the "don't fragment" bit. This option is valid only on IPv4.</p>
<code>-f first_hop</code>	<p>Set the starting <code>tll (hop limit)</code> value to <code>first_hop</code>, to override the default value 1. <code>tracertool</code> skips processing for those intermediate gateways which are less than <code>first_hop</code> hops away.</p>
<code>-g gateway</code>	<p>Specify a loose source route <code>gateway</code>. The user can specify more than one <code>gateway</code> by using <code>-g</code> for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the <code>-r</code> option.</p>
<code>-I</code>	<p>Use ICMP (ICMP6) ECHO instead of UDP datagrams.</p>
<code>-i iface</code>	<p>For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The <code>-s</code> option is also another way to do this. For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, <code>le0</code>, <code>hme0</code>.</p>
<code>-L flow_label</code>	<p>Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.</p>
<code>-l</code>	<p>Print the value of the <code>tll (hop limit)</code> field in each packet received.</p>
<code>-m max_hop</code>	<p>Set the maximum <code>tll (hop limit)</code> used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.</p>

traceroute(1M)

-n	Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.
-P <i>pause_sec</i>	Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, <code>traceroute</code> sends the next probe as soon as it has received a reply. Note that <i>pause_sec</i> is a real number.
-p <i>port</i>	Set the base UDP <i>port</i> number used in probes. The default is 33434. <code>traceroute</code> hopes that nothing is listening on UDP <i>ports</i> (base+ (nhops-1) *nqueries) to (base+ (nhops*nqueries) -1) at the destination host, so that an ICMP (ICMP6) <code>PORT_UNREACHABLE</code> message will be returned to terminate the route tracing. If something is listening on a <i>port</i> in the default range, this option can be used to select an unused <i>port</i> range. <i>nhops</i> is defined as the number of hops between the source and the destination.
-Q <i>max_timeout</i>	Stop probing this hop after <i>max_timeout</i> consecutive timeouts are detected. The default value is 5. Useful in combination with the -q option if you have specified a large <i>nqueries</i> probe count.
-q <i>nqueries</i>	Set the desired number of probe queries. The default is 3.
-r	Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See in <code>routed(1M)</code> . You cannot use this option if the -g option is used.
-s <i>src_addr</i>	Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address <code>traceroute</code> picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the -i option, the given IP address should be configured on the specified

interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

<code>-t tos</code>	Set the <i>tos</i> (type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the <i>tos</i> value set in the probe packet. This option is valid only on IPv4.
<code>-v</code>	Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than <code>TIME_EXCEEDED</code> and <code>UNREACHABLE</code> are listed as well.
<code>-w waittime</code>	Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.
<code>-x</code>	Prevent <code>tracert</code> from calculating checksums. Note that checksums are usually required for the last hop when using ICMP ECHO probes. This option is valid only on IPv4. See the <code>-I</code> option.

OPERANDS The following operands are supported:

host The network host.

EXAMPLES **EXAMPLE 1** Sample Output From the `tracert` Utility

Some sample output from the `tracert` utility might be:

```
istanbul% tracert london
tracert: Warning: london has multiple addresses; \
  using 4::114:a00:20ff:ab3d:83ed
tracert: Warning: Multiple interfaces found; \
  using 4::56:a00:20ff:fe93:8dde @ le0:2
tracert to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \
  60 byte packets
 1 frbldg7c-86 (4::56:a00:20ff:fe1f:65a1)  1.786 ms  1.544 ms  1.719 ms
 2 frbldg7b-77 (4::255:0:0:c0a8:517)  2.587 ms  3.001 ms  2.988 ms
 3 london (4::114:a00:20ff:ab3d:83ed)  3.122 ms  2.744 ms  3.356 ms
```

The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, `tracert` uses IPv6 address of the destination host.

EXAMPLE 2 Using the `tracert` Utility For a Host Which has Only IPv4 Addresses

In the following examples, `tracert` is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore `tracert` uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

traceroute(1M)

EXAMPLE 2 Using the traceroute Utility For a Host Which has Only IPv4 Addresses (Continued)

```
istanbul% traceroute sanfrancisco
traceroute: Warning: Multiple interfaces found; using 172.31.86.247 @ le0
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
 1 frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
 2 bldg1a-001 (172.31.1.211)  2.277 ms  1.773 ms  2.186 ms
 3 bldg4-bldg1 (172.30.4.42)  1.978 ms  1.986 ms  13.996 ms
 4 bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
 5 ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
 6 frbldg12b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
 7 sanfrancisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 3 Using the traceroute Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the `-g` option. The `-I` option makes `traceroute` send ICMP ECHO probes to the host sanfrancisco. The `-i` options sets the source address to the IP address configured on the interface `qe0`.

```
istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
 1 frbldg7c-86 (172.31.86.1)  2.012 ms
 2 flrbldg7u (172.31.17.131)  4.960 ms
 3 cairo (192.168.163.175)  4.894 ms
 4 flrbldg7u (172.31.17.131)  3.475 ms
 5 frbldg7c-017 (172.31.17.83)  4.126 ms
 6 paris (172.31.86.31)  4.086 ms
 7 frbldg7b-82 (172.31.82.1)  6.454 ms
 8 bldg1a-001 (172.31.1.211)  6.541 ms
 9 bldg6-bldg4 (172.30.4.49)  6.518 ms
10 ferbldg11a-001 (172.29.1.236)  9.108 ms
11 frbldg12b-153 (172.29.153.72)  9.634 ms
12 sanfrancisco (172.29.64.39)  14.631 ms
```

EXIT STATUS The following exit values are returned:

0 Successful operation.
>0 An error occurred.

WARNINGS This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use `traceroute(1M)` during normal operations or from automated scripts.

ttyadm(1M)

NAME	ttyadm – format and output port monitor-specific information																				
SYNOPSIS	<pre>/usr/sbin/ttyadm [-b] [-c] [-h] [-I] [-r <i>count</i>] [-i <i>msg</i>] [-m <i>modules</i>] [-p <i>prompt</i>] [-t <i>timeout</i>] [-S y n] [-T <i>termtype</i>] -d <i>device</i> -l <i>ttylabel</i> -s <i>service</i> /usr/sbin/ttyadm -V</pre>																				
DESCRIPTION	The <code>ttyadm</code> command is an administrative command that formats <code>ttymon(1M)</code> -specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller's administrative commands, <code>sacadm(1M)</code> and <code>pmadm(1M)</code> . <code>ttyadm</code> provides a means of presenting formatted port monitor-specific (<code>ttymon</code> -specific) data to these commands.																				
OPTIONS	<table><tr><td>-b</td><td>Set the "bi-directional port" flag. When this flag is set, the line can be used in both directions. <code>ttymon</code> will allow users to connect to the service associated with the port, but if the port is free, <code>uucico(1M)</code>, <code>cu(1C)</code>, or <code>ct(1C)</code> can use it for dialing out.</td></tr><tr><td>-c</td><td>Set the connect-on-carrier flag for the port. If the <code>-c</code> flag is set, <code>ttymon</code> will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).</td></tr><tr><td>-h</td><td>Set the hangup flag for the port. If the <code>-h</code> flag is not set, <code>ttymon</code> will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.</td></tr><tr><td>-I</td><td>Initialize only. If the <code>-I</code> option is used, <code>ttymon</code> will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.</td></tr><tr><td>-d <i>device</i></td><td><i>device</i> is the full pathname of the device file for the TTY port.</td></tr><tr><td>-i <i>message</i></td><td>Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the <code>ttymon</code> monitoring the port is disabled.</td></tr><tr><td>-l <i>ttylabel</i></td><td>Specify which <i>ttylabel</i> in the <code>/etc/ttydefs</code> file to use as the starting point when searching for the proper baud rate.</td></tr><tr><td>-m <i>modules</i></td><td>Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. <i>modules</i> must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.</td></tr><tr><td>-p <i>prompt</i></td><td>Specify the prompt message, for example, "login:".</td></tr><tr><td>-r <i>count</i></td><td>When the <code>-r</code> option is invoked, <code>ttymon</code> will wait until it receives data from the port before it displays a prompt. If <i>count</i> is 0,</td></tr></table>	-b	Set the "bi-directional port" flag. When this flag is set, the line can be used in both directions. <code>ttymon</code> will allow users to connect to the service associated with the port, but if the port is free, <code>uucico(1M)</code> , <code>cu(1C)</code> , or <code>ct(1C)</code> can use it for dialing out.	-c	Set the connect-on-carrier flag for the port. If the <code>-c</code> flag is set, <code>ttymon</code> will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).	-h	Set the hangup flag for the port. If the <code>-h</code> flag is not set, <code>ttymon</code> will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.	-I	Initialize only. If the <code>-I</code> option is used, <code>ttymon</code> will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.	-d <i>device</i>	<i>device</i> is the full pathname of the device file for the TTY port.	-i <i>message</i>	Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the <code>ttymon</code> monitoring the port is disabled.	-l <i>ttylabel</i>	Specify which <i>ttylabel</i> in the <code>/etc/ttydefs</code> file to use as the starting point when searching for the proper baud rate.	-m <i>modules</i>	Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. <i>modules</i> must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.	-p <i>prompt</i>	Specify the prompt message, for example, "login:".	-r <i>count</i>	When the <code>-r</code> option is invoked, <code>ttymon</code> will wait until it receives data from the port before it displays a prompt. If <i>count</i> is 0,
-b	Set the "bi-directional port" flag. When this flag is set, the line can be used in both directions. <code>ttymon</code> will allow users to connect to the service associated with the port, but if the port is free, <code>uucico(1M)</code> , <code>cu(1C)</code> , or <code>ct(1C)</code> can use it for dialing out.																				
-c	Set the connect-on-carrier flag for the port. If the <code>-c</code> flag is set, <code>ttymon</code> will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).																				
-h	Set the hangup flag for the port. If the <code>-h</code> flag is not set, <code>ttymon</code> will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.																				
-I	Initialize only. If the <code>-I</code> option is used, <code>ttymon</code> will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.																				
-d <i>device</i>	<i>device</i> is the full pathname of the device file for the TTY port.																				
-i <i>message</i>	Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the <code>ttymon</code> monitoring the port is disabled.																				
-l <i>ttylabel</i>	Specify which <i>ttylabel</i> in the <code>/etc/ttydefs</code> file to use as the starting point when searching for the proper baud rate.																				
-m <i>modules</i>	Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. <i>modules</i> must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.																				
-p <i>prompt</i>	Specify the prompt message, for example, "login:".																				
-r <i>count</i>	When the <code>-r</code> option is invoked, <code>ttymon</code> will wait until it receives data from the port before it displays a prompt. If <i>count</i> is 0,																				

- ttymon will wait until it receives any character. If *count* is greater than 0, ttymon will wait until *count* newlines have been received.
- s *service* *service* is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes ("").
 - t *timeout* Specify that ttymon should close a port if the open on the port succeeds, and no input data is received in *timeout* seconds.
 - S *y|n* Set the software carrier value. *y* will turn software carrier on. *n* will turn software carrier off.
 - T *termtype* Set the terminal type. The TERM environment variable will be set to *termtype*.
 - V Display the version number of the current /usr/lib/saf/ttymon command.

OUTPUT If successful, ttyadm will generate the requested information, write it to standard output, and exit with a status of 0. If ttyadm is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and ttymon will exit with a non-zero status.

ttymon(1M)

NAME	ttymon – port monitor for terminal ports
SYNOPSIS	<pre>/usr/lib/saf/ttymon /usr/lib/saf/ttymon -g [-d device] [-h] [-t timeout] [-l ttylabel] [-p prompt] [-m modules] [-T termtype]</pre>
DESCRIPTION	<p>ttymon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, ttymon is configured to run under the Service Access Controller, sac(1M), as part of the Service Access Facility (SAF). It is configured using the sacadm(1M) command. Each instance of ttymon can monitor multiple ports. The ports monitored by an instance of ttymon are specified in the port monitor's administrative file. The administrative file is configured using the pmadm(1M) and ttyadm(1M) commands. When an instance of ttymon is invoked by the sac command, it starts to monitor its ports. For each port, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See logindevperm(4).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the sttydefs(1M) command. Default line disciplines on ports are usually set up by the autopush(1M) command of the Autopush Facility.</p> <p>ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon interprets the per-service configuration file for the port, if one exists, creates a utmpx entry if required (see utmpx(4)), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, ttymon cleans up the utmpx entry, if one exists, and returns the port to its initial state.</p> <p>If <i>autobaud</i> is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by <i>autobaud</i> are 110, 1200, 2400, 4800, and 9600.</p> <p>If a port is configured as a bidirectional port, ttymon will allow users to connect to a service, and, if the port is free, will allow uucico(1M), cu(1C), or ct(1C) to use it for dialing out. If a port is bidirectional, ttymon will wait to read a character before it prints a prompt.</p> <p>If the <i>connect-on-carrier</i> flag is set for a port, ttymon will immediately invoke the port's associated service when a connection request is received. The prompt message will not be sent.</p>

**SERVICE
INVOCATION**

If a port is disabled, ttypmon will not start any service on that port. If a disabled message is specified, ttypmon will send out the disabled message when a connection request is received. If ttypmon is disabled, all ports under that instance of ttypmon will also be disabled.

The service ttypmon invokes for a port is specified in the ttypmon administrative file. ttypmon will scan the character string giving the service to be invoked for this port, looking for a %d or a %% two-character sequence. If %d is found, ttypmon will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If %% is found, they will be replaced by a single %. When the service is invoked, file descriptor 0, 1, and 2 are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with ttypmon. Two environment variables, HOME and TTYPROMPT, are added to the service's environment by ttypmon. HOME is set to the home directory of the user name under which the service is invoked. TTYPROMPT is set to the prompt string configured for the service on the port. This is provided so that a service invoked by ttypmon has a means of determining if a prompt was actually issued by ttypmon and, if so, what that prompt actually was.

See ttyadm(1M) for options that can be set for ports monitored by ttypmon under the Service Access Controller.

SECURITY

ttypmon uses pam(3PAM) for session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for ttypmon. Here is a partial pam.conf file with entries for ttypmon using the UNIX session management module.

```
ttypmon session required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the ttypmon service, then the entries for the "other" service will be used.

OPTIONS

- g A special invocation of ttypmon is provided with the -g option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to login service, but that cannot be pre-configured under the SAC. The following combinations of options can be used with -g:
- d *device* *device* is the full path name of the port to which ttypmon is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.
- h If the -h flag is not set, ttypmon will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.
- l *ttylabel* *ttylabel* is a link to a speed and TTY definition in the ttydefs file. This definition tells ttypmon at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user

ttymon(1M)

- indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.
- m *modules* When initializing the port, *ttymon* will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.
 - p *prompt* Allows the user to specify a prompt string. The default prompt is Login: .
 - t *timeout* Specifies that *ttymon* should exit if no one types anything in *timeout* seconds after the prompt is sent.
 - T *termtype* Sets the TERM environment variable to *termtype*.

ENVIRONMENT VARIABLES

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see *environ(5)*) are not set in the environment, the operational behavior of *ttymon* for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how *ttymon* behaves.

LC_CTYPE Determines how *ttymon* handles characters. When LC_CTYPE is set to a valid value, *ttymon* can display and handle text and filenames containing valid characters for that locale. *ttymon* can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. *ttymon* can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

NOTES

If a port is monitored by more than one *ttymon*, it is possible for the *ttymons* to send out prompt messages in such a way that they compete for input.

NAME	tunefs – tune up an existing file system
SYNOPSIS	tunefs [-a <i>maxcontig</i>] [-d <i>rotdelay</i>] [-e <i>maxbpg</i>] [-m <i>minfree</i>] [-o [space time]] <i>special</i> <i>filesystem</i>
DESCRIPTION	<p>tunefs is designed to change the dynamic parameters of a file system which affect the layout policies. When using tunefs with <i>filesystem</i>, <i>filesystem</i> must be in <i>/etc/vfstab</i>. The parameters which are to be changed are indicated by the options given below.</p> <p>Generally one should optimize for time unless the file system is over 90% full.</p>
OPTIONS	<p>-a <i>maxcontig</i> Specify the maximum number of contiguous blocks that will be laid out before forcing a rotational delay (see -d). The default value is determined from the disk drive's maximum transfer rate. The maximum <i>maxconfig</i> that UFS supports is 10486576.</p> <p>-d <i>rotdelay</i> Specify the expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. It is used to decide how much rotational spacing to place between successive blocks in a file.</p> <p>-e <i>maxbpg</i> Indicate the maximum number of blocks any single file can allocate out of a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group. The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.</p> <p>-m <i>minfree</i> Specify the percentage of space held back from normal users; the minimum free space threshold. This value can be set to 0, however up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. Note: If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.</p> <p>-o [space time] Change optimization strategy for the file system.</p> <p>space: conserve space</p> <p>time: attempt to organize file layout to minimize access time</p>
USAGE	See <i>largefile(5)</i> for the description of the behavior of tunefs when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).

NAME	uadmin – administrative control				
SYNOPSIS	<code>/usr/sbin/uadmin cmd fcn [mdep]</code> <code>/sbin/uadmin cmd fcn [mdep]</code>				
DESCRIPTION	<p>The <code>uadmin</code> command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.</p> <p>Both the <i>cmd</i> (command) and <i>fcn</i> (function) arguments are converted to integers and passed to the <code>uadmin</code> system call. The optional <i>mdep</i> (machine dependent) argument is only available for the <i>cmd</i> values of 1 (<code>A_REBOOT</code>) or 2 (<code>A_SHUTDOWN</code>), to pass a single string of boot arguments to the <code>uadmin</code> system call. For any other <i>cmd</i> value, no <i>mdep</i> command-line argument is allowed.</p> <p>When passing an <i>mdep</i> value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes (for example, <code>uadmin 1 1 "-s kernel/unix"</code>).</p>

ufsdump(1M)

NAME	ufsdump – incremental file system dump
SYNOPSIS	<code>/usr/sbin/ufsdump</code> [<i>options</i>] [<i>arguments</i>] <i>files_to_dump</i>
DESCRIPTION	<p>ufsdump backs up all files specified by <i>files_to_dump</i> (normally either a whole file system or files within a file system changed after a certain date) to magnetic tape, diskette, or disk file. When running ufsdump, the file system must be inactive; otherwise, the output of ufsdump may be inconsistent and restoring files correctly may be impossible. A file system is inactive when it is unmounted or the system is in single user mode. A file system is not considered inactive if one tree of the file system is quiescent while another tree has files or directories being modified.</p> <p><i>options</i> is a single string of one-letter ufsdump options.</p> <p><i>arguments</i> may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.</p> <p><i>files_to_dump</i> is required and must be the last argument on the command line. See OPERANDS for more information.</p> <p>With most devices ufsdump can automatically detect the end-of-media. Consequently, the <i>d</i>, <i>s</i>, and <i>t</i> options are not necessary for multi-volume dumps, unless ufsdump does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the <i>restore</i> command.</p>
OPTIONS	<p>The following options are supported:</p> <p><i>0-9</i> The “dump level.” All files specified by <i>files_to_dump</i> that have been modified since the last ufsdump at a lower dump level are copied to the <i>dump_file</i> destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the <i>dump_file</i>.</p> <p><i>a archive_file</i> Archive file. Archive a dump table-of-contents in the specified <i>archive_file</i> to be used by <i>ufsrestore(1M)</i> to determine whether a file is in the dump file that is being restored.</p> <p><i>b factor</i> Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (<i>c</i> option) is 126. The highest blocking factor available</p>

	with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with <code>tar(1)</code> .
<code>c</code>	Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since <code>ufsdump</code> can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is <i>not</i> specified, <code>ufsdump</code> will slightly miscalculate the size of the tape. If the <code>b</code> , <code>d</code> , <code>s</code> or <code>t</code> options are specified with this option, their values will override the defaults set by this option.
<code>d bpi</code>	Tape density. Not normally required, as <code>ufsdump</code> can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the <code>c</code> option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are: 1/2 inch tape 6250 BPI 1/4 inch cartridge 1000 BPI The tape densities and other options are documented in the <code>st(7D)</code> man page.
<code>D</code>	Diskette. Dump to diskette.
<code>f dump_file</code>	Dump file. Use <code>dump_file</code> as the file to dump to, instead of <code>/dev/rmt/0</code> . If <code>dump_file</code> is specified as <code>-</code> , dump to standard output. If the name of the file is of the form <code>machine:device</code> , the dump is done from the specified machine over the network using <code>rmt(1M)</code> . Since <code>ufsdump</code> is normally run by root, the name of the local machine must appear in the <code>.rhosts</code> file of the remote machine. If the file is specified as <code>user@machine:device</code> , <code>ufsdump</code> will attempt to execute as the specified user on the remote machine. The specified user must have a <code>.rhosts</code> file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.
<code>l</code>	Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to

ufsdump(1M)

	<p>two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.</p>
L <i>string</i>	<p>Sets the tape label to <i>string</i>, instead of the default <i>none</i>. <i>string</i> may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the <code>ufsdump</code> tape format, and bears no resemblance to IBM or ANSI-standard tape labels.</p>
N <i>device_name</i>	<p>Use <i>device_name</i> when recording information in <code>/etc/dumpdates</code> (see the <code>u</code> option) and when comparing against information in <code>/etc/dumpdates</code> for incremental dumps. The <i>device_name</i> provided can contain no white space as defined in <code>scanf(3C)</code> and is case-sensitive.</p>
n	<p>Notify all operators in the <code>sys</code> group that <code>ufsdump</code> requires attention by sending messages to their terminals, in a manner similar to that used by the <code>wall(1M)</code> command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running <code>ufsdump</code> is logged in.</p>
o	<p>Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.</p>
s <i>size</i>	<p>Specify the <i>size</i> of the volume being dumped to. Not normally required, as <code>ufsdump</code> can detect end-of-media. When the specified size is reached, <code>ufsdump</code> waits for you to change the volume. <code>ufsdump</code> interprets the specified size as the length in feet for tapes and cartridges, and as the number of 1024-byte blocks for diskettes. The values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the <code>c</code> option, for cartridge devices, and the <code>D</code> option for diskettes:</p> <p>1/2 inch tape 2300 feet</p>

	60-Mbyte 1/4 inch cartridge 425 feet
	150-Mbyte 1/4 inch cartridge 700 feet
	diskette 1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad block information.)
S	Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.
t <i>tracks</i>	Specify the number of tracks for a cartridge tape. Not normally required, as <code>ufsdump</code> can detect end-of-media. The default is 9 tracks. The <code>t</code> option is not compatible with the <code>D</code> option. Values for Sun-supported tape devices are: 60-Mbyte 1/4 inch cartridge 9 tracks 150-Mbyte 1/4 inch cartridge 18 tracks
T <i>time_wait</i> [hms]	Sets the amount of time to wait for an <code>autoload</code> command to complete. This option is ignored unless the <code>l</code> option has also been specified. The default time period to wait is two minutes. Specify time units with a trailing <code>h</code> (for hours), <code>m</code> (for minutes), or <code>s</code> (for seconds). The default unit is minutes.
u	Update the dump record. Add an entry to the file <code>/etc/dumpdates</code> , for each file system successfully dumped that includes the file system name (or <i>device_name</i> as specified with the <code>N</code> option), date, and dump level.
v	Verify. After each tape or diskette is written, verify the contents of the media against the source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system <i>must</i> be unmounted. This option cannot be used to verify a dump to standard output.
w	Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files <code>/etc/dumpdates</code> and <code>/etc/vfstab</code> . When the <code>w</code> option is used, all other options are ignored. After reporting, <code>ufsdump</code> exits immediately.

ufsdump(1M)

	w	Warning with highlight. Similar to the w option, except that the W option includes all file systems that appear in <code>/etc/dumpdates</code> , along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.
OPERANDS	The following operand is supported:	
	<i>files_to_dump</i>	Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, <code>/dev/rdisk/c0t3d0s6</code>). Incremental dumps (levels 1 to 9) of files changed after a certain date only apply to a whole file system. Alternatively, <i>files_to_dump</i> can identify individual files or directories. All named directories that may be examined by the user running <code>ufsdump</code> , as well as any explicitly-named files, are dumped. This dump is equivalent to a level 0 dump of the indicated portions of the filesystem, except that <code>/etc/dumpdates</code> is not updated even if the <code>-u</code> option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where <code>ufsdump</code> is being run. <i>files_to_dump</i> is required and must be the last argument on the command line. If no <i>options</i> are given, the default is <code>9uf /dev/rmt/0 files_to_dump</code> .
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>ufsdump</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
EXAMPLES	EXAMPLE 1 A sample display of the <code>ufsdump</code> command. To make a full dump of a root file system on <code>c0t3d0</code> , on a 150-MByte cartridge tape unit 0, use: <pre>example# ufsdump 0cfu /dev/rmt/0 /dev/rdisk/c0t3d0s0</pre> To make and verify an incremental dump at level 5 of the <code>usr</code> partition of <code>c0t3d0</code> , on a 1/2 inch reel tape unit 1, use: <pre>example# ufsdump 5fuv /dev/rmt/1 /dev/rdisk/c0t3d0s6</pre>	
EXIT STATUS	While running, <code>ufsdump</code> emits many verbose messages. <code>ufsdump</code> returns the following exit values:	
	0	Normal exit.
	1	Startup errors encountered.
	3	Abort – no checkpoint attempted.
FILES	<code>/dev/rmt/0</code>	default unit to dump to

/etc/dumpdates dump date record
 /etc/group to find group *sys*
 /etc/hosts to gain access to remote system with drive
 /etc/vfstab list of file systems

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `cpio(1)`, `tar(1)`, `dd(1M)`, `devnm(1M)`, `prtvtoc(1M)`, `rmt(1M)`, `shutdown(1M)`, `ufsrestore(1M)`, `volcopy(1M)`, `wall(1M)`, `attributes(5)`, `largefile(5)`, `st(7D)`

Read Errors Fewer than 32 read errors on the file system are ignored.

Process Per Reel Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

Operator Intervention `ufsdump` requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the `n` option, `ufsdump` interacts with the operator on `ufsdump`'s control terminal at times when `ufsdump` can no longer proceed, or if something is grossly wrong. All questions `ufsdump` poses *must* be answered by typing *yes* or *no*, as appropriate.

Since backing up a disk can involve a lot of time and effort, `ufsdump` checkpoints at the start of each volume. If writing that volume fails for some reason, `ufsdump` will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

Suggested Dump Schedule It is vital to perform full, "level 0", dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using `shutdown(1M)`. While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

ufsdump(1M)

	Sun	Mon	Tue	Wed	Thu	Fri
Week 1:	Full	5	5	5	5	3
Week 2:		5	5	5	5	3
Week 3:		5	5	5	5	3
Week 4:		5	5	5	5	3

Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day’s incremental dump.

Process Priority of ufsdump

ufsdump uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a `nice` (process priority) of `-5` or better will likely make ufsdump run *slower* instead of faster.

Overlapping Partitions

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places `root` on slice 0, `swap` on slice 1, `/opt` on slice 5 and `/usr` on slice 6.

It should be emphasized that ufsdump dumps one `ufs` file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing ufsdump on slice 2 with the intent of dumping the entire disk would instead dump only the `root` file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

BUGS

The `/etc/vfstab` file does not allow the desired frequency of backup for file systems to be specified (as `/etc/fstab` did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.

NAME	ufsrestore – incremental file system restore
SYNOPSIS	<code>/usr/sbin/ufsrestore i r R t x [abcdfhlmstvyLT] [archive_file] [factor] [dumpfile] [n] [label] [timeout] [filename...]</code>
DESCRIPTION	<p>The <code>ufsrestore</code> utility restores files from backup media created with the <code>ufsdump</code> command. <code>ufsrestore</code>'s actions are controlled by the <i>key</i> argument. The <i>key</i> is exactly one function <i>letter</i> (<i>i</i>, <i>r</i>, <i>R</i>, <i>t</i>, or <i>x</i>) and zero or more <i>function modifiers</i> (letters). The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string.</p> <p><i>filename</i> arguments which appear on the command line, or as arguments to an interactive command, are treated as shell <code>glob</code> patterns by the <i>x</i> and <i>t</i> functions; any files or directories matching the patterns are selected. The metacharacters <code>*</code>, <code>?</code>, and <code>[]</code> must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.</p> <p>The temporary files <code>rstdir*</code> and <code>rstmode*</code> are placed in <code>/tmp</code> by default. If the environment variable <code>TMPDIR</code> is defined with a non-empty value, that location is used instead of <code>/tmp</code>.</p>
Function Letters	<p>One (and only one) of the following function letters is required:</p> <p><i>i</i> Interactive. After reading in the directory information from the media, <code>ufsrestore</code> invokes an interactive interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. See <i>Interactive Commands</i>, below, for a description of available commands.</p> <p><i>r</i> Recursive. Restore the entire contents of the dumped file system into the current directory (which should be the top-level of the file system). To completely restore a file system, use this function letter to restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a clear file system, if the file system contains files not on the dump, they are preserved.</p> <p><i>R</i> Resume restoring. <code>ufsrestore</code> requests a particular volume of a multi-volume set from which to resume a full restore (see the <i>r</i> function letter above). This allows <code>ufsrestore</code> to start from a checkpoint when it is interrupted in the middle of a full restore.</p> <p><i>t</i> Table of contents. List each <i>filename</i> that appears on the media. If no <i>filename</i> argument is given, the root directory is listed. This results in a list of all files on the media, unless the <i>h</i> function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the <i>a</i> function modifier is used. This function modifier is mutually exclusive with the <i>x</i> and <i>r</i> function letters.</p> <p><i>x</i> Extract the named files from the media. If a named file matches a directory whose contents were written onto the media, and the <i>h</i> modifier is not in</p>

ufsrestore(1M)

		<p>effect, the directory is recursively extracted. The owner, modification time, and mode are restored (if possible). Existing files are overwritten and a warning is given. If no <i>filename</i> argument is given, the root directory is extracted. This results in the entire tape being extracted unless the <i>h</i> modifier is in effect. Use the <i>x</i> option to restore partial file system dumps, as they are (by definition) not entire file systems.</p>
Function Modifiers	<i>a archive_file</i>	<p>Read the table of contents from <i>archive_file</i> instead of the media. This function modifier can be used in combination with the <i>t</i>, <i>i</i>, or <i>x</i> function letters, making it possible to check whether files are on the media without having to mount the media. When used with the <i>x</i> and interactive (<i>i</i>) function letters, it prompts for the volume containing the file(s) before extracting them.</p>
	<i>b factor</i>	<p>Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.</p>
	<i>c</i>	<p>Convert the contents of the media in 4.1BSD format to the new <i>ufs</i> file system format.</p>
	<i>d</i>	<p>Debug. Turn on debugging output.</p>
	<i>f dump_file</i>	<p>Use <i>dump_file</i> instead of <code>/dev/rmt/0</code> as the file to restore from. Typically <i>dump_file</i> specifies a tape or diskette drive. If <i>dump_file</i> is specified as <code>'-'</code>, <i>ufsrestore</i> reads from the standard input. This allows <i>ufsdump(1M)</i> and <i>ufsrestore</i> to be used in a pipeline to copy a file system:</p> <pre>example# ufsdump 0f - /dev/rdisk/c0t0d0s7 \ (cd /home;ufsrestore xf -)</pre> <p>If the name of the file is of the form <i>machine:device</i>, the restore is done from the specified machine over the network using <i>rmt(1M)</i>. Since <i>ufsrestore</i> is normally run by root, the name of the local machine must appear in the <code>.rhosts</code> file of the remote machine. If the file is specified as <i>user@machine:device</i>, <i>ufsrestore</i> will attempt to execute as the specified user on the remote machine. The specified user must have a <code>.rhosts</code> file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.</p>
	<i>h</i>	<p>Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.</p>

l	Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the T function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
L <i>label</i>	The label that should appear in the header of the dump file. If the labels do not match, <code>ufsrestore</code> issues a diagnostic and exits. The tape label is specific to the <code>ufsdump</code> tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
m	Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.
o	Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.
s <i>n</i>	<p>Skip to the <i>n</i>'th file when there are multiple dump files on the same tape. For example, the command:</p> <pre>example# ufsrestore xfs /dev/rmt/0hn 5</pre> <p>would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "s <i>n</i>" value is specified.</p> <p>If "s <i>n</i>" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward <i>n</i> - 1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.</p>
T timeout [hms]	Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.
v	Verbose. <code>ufsrestore</code> displays the name and inode number of each file it restores, preceded by its file type.
y	Do not ask whether to abort the restore in the event of tape errors. <code>ufsrestore</code> tries to skip over the bad tape block(s) and continue

ufsrestore(1M)

as best it can.

Interactive Commands

`ufsrestore` enters interactive mode when invoked with the `i` function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

<code>add [filename]</code>	Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the <code>h</code> modifier is in effect).
<code>cd directory</code>	Change to <i>directory</i> (within the dump file).
<code>delete [filename]</code>	Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the <code>h</code> modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.
<code>extract</code>	Extract all files on the extraction list from the dump media. <code>ufsrestore</code> asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If " <code>s n</code> " is given on the command line, volume 1 will automatically be positioned to file <code>n</code> when it is read.
<code>help</code>	Display a summary of the available commands.
<code>ls [directory]</code>	List files in <i>directory</i> or the current directory, represented by a <code>'.'</code> (period). Directories are appended with a <code>'/'</code> (slash). Entries marked for extraction are prefixed with a <code>'*'</code> (asterisk). If the verbose option is in effect, inode numbers are also listed.
<code>marked [directory]</code>	Like <code>ls</code> , except only files marked for extraction are listed.
<code>pager</code>	Toggle the pagination of the output from the <code>ls</code> and <code>marked</code> commands. The pager used is that defined by the <code>PAGER</code> environment variable, or <code>more(1)</code> if that <code>envar</code> is not defined. The <code>PAGER</code> <code>envar</code> may include white-space-separated arguments for the pagination program.
<code>pwd</code>	Print the full pathname of the current working directory.
<code>quit</code>	<code>ufsrestore</code> exits immediately, even if the extraction list is not empty.

	setmodes	Prompts: set owner/mode for '.' (period). Type y for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type n for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.
	setpager <i>command</i>	Sets the command to use for paginating output instead of the default or that inherited from the environment. The <i>command</i> string may include arguments in addition to the command itself.
	verbose	Toggle the status of the v modifier. While v is in effect, the ls command lists the inode numbers of all entries, and ufsrestore displays information about each file as it is extracted.
	what	Display the dump header on the media.
OPERANDS	The following operands are supported.	
	<i>filename</i>	Specifies the pathname of files (or directories) to be restored to disk. Unless the h function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. <i>filename</i> is associated with either the x or t function letters, and must come last.
USAGE	See largefile(5) for the description of the behavior of ufsrestore when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).	
EXIT STATUS	The following exit values are returned:	
	0	Successful completion.
	1	An error occurred. Verbose messages are displayed.
ENVIRONMENT VARIABLES	PAGER	The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is more(1).
	TMPDIR	Selects the directory for temporary files. Defaults to /tmp if not defined in the environment.
FILES	/dev/rmt/0	the default tape drive
	\$TMPDIR/rst [*] dir	file containing directories on the tape
	\$TMPDIR/rst [*] mode	owner, mode, and timestamps for directories

ufsrestore(1M)

`./restoresymtable` information passed between incremental restores

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `more(1)`, `mkfs(1M)`, `mount(1M)`, `rmt(1M)`, `ufsdump(1M)`, `attributes(5)`, `largefile(5)`

DIAGNOSTICS `ufsrestore` complains about bad option characters.

Read errors result in complaints. If `y` has been specified, or the user responds `y`, `ufsrestore` will attempt to continue.

If the dump extends over more than one tape, `ufsrestore` asks the user to change tapes. If the `x` or `i` function letter has been specified, `ufsrestore` also asks which volume the user wishes to mount. If the `s` modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by `ufsrestore`. Most checks are self-explanatory or can “never happen”. Common errors are given below.

Converting to new file system format

A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape

The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the `r` function.

expected next file *inumber*, got *inumber*

A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low

When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

Incremental tape too high

When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument

Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring *filename*

Tape read error while skipping over inode *inumber*

Tape read error while trying to resynchronize

A tape read error has occurred

If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

resync ufsrestore, skipped *num*

After a tape read error, ufsrestore may have to resynchronize itself. This message lists the number of blocks that were skipped over.

Incorrect tape label. Expected 'foo', got 'bar'.

The L option was specified, and its value did not match what was recorded in the header of the dump file.

NOTES ufsrestore can get confused when doing incremental restores from dump tapes that were made on active file systems.

A level 0 dump must be done after a full restore. Because ufsrestore runs in user mode, it has no control over inode allocation. This means that ufsrestore repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

unshare(1M)

- NAME** unshare – make local resource unavailable for mounting by remote systems
- SYNOPSIS** **unshare** [-F *FSType*] [-o *specific_options*] [*pathname* | *resourcename*]
- DESCRIPTION** The unshare command makes a shared local resource unavailable as file system type *FSType*. If the option -F *FSType* is omitted, then the first file system type listed in file */etc/dfs/fstypes* will be used as the default. *Specific_options*, as well as the semantics of *resourcename*, are specific to particular distributed file systems.
- OPTIONS**
- | | |
|----------------------------|--|
| -F <i>FSType</i> | Specify the file system type. |
| -o <i>specific_options</i> | Specify options specific to the file system provided by the -F option. |
- FILES**
- /etc/dfs/fstypes*
 - /etc/dfs/sharetab*
- ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *share(1M)*, *shareall(1M)*, *attributes(5)*

NOTES If *pathname* or *resourcename* is not found in the shared information, an error message will be sent to standard error.

- NAME** unshare_nfs – make local NFS file systems unavailable for mounting by remote systems
- SYNOPSIS** **unshare** [-F nfs] *pathname*
- DESCRIPTION** The unshare command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the *FSType* in the file */etc/dfs/sharetab*.
- OPTIONS** The following options are supported:
- F This option may be omitted if NFS is the first file system type listed in the file */etc/dfs/fstypes*.
- FILES** */etc/dfs/fstypes*
/etc/dfs/sharetab
- ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *share(1M)*, *attributes(5)*

NOTES If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if */export/foo* is a symbolic link to */export/bar* (*/export/foo* -> */export/bar*), the following unshare command will result in */export/bar* as the unshared pathname (and not */export/foo*):

```
example# unshare -F nfs /export/foo
```

useradd(1M)

NAME	useradd – administer a new user login on the system						
SYNOPSIS	<pre>useradd [-c <i>comment</i>] [-d <i>dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i>...]] [-m [-k <i>skel_dir</i>]] [-u <i>uid</i> [-o]] [-s <i>shell</i>] [-A <i>authorization</i> [, <i>authorization</i>...]] [-P <i>profile</i> [, <i>profile</i>...]] [-R <i>role</i> [, <i>role</i>...]] [-p <i>projname</i>] <i>login</i> useradd -D [-b <i>base_dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-p <i>projname</i>]</pre>						
DESCRIPTION	<p>useradd adds a new user to the /etc/passwd and /etc/shadow and /etc/user_attr files. The -A and -P options respectively assign authorizations and profiles to the user. The -R option assigns roles to a user. The -p option associates a project with a user.</p> <p>useradd also creates supplementary group memberships for the user (-G option) and creates the home directory (-m option) for the user if requested. The new login remains locked until the passwd(1) command is executed.</p> <p>Specifying useradd -D with the -g, -b, -f, -e, -A, -P, -p, or -R option (or any combination of these options) sets the default values for the respective fields. See the -D option, below. Subsequent useradd commands without the -D option use these arguments.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.</p> <p>The login (<i>login</i>) and role (<i>role</i>) fields accept a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underscore (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login and role fields that do not meet these requirements.</p> <p>The <i>login</i> and <i>role</i> fields must contain at least one character and must not contain a colon (:) or a newline (\n).</p>						
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-A <i>authorization</i></td><td>One or more comma separated authorizations defined in <i>auth_attr</i>(4). Only a user or role who has <i>grant</i> rights to the authorization can assign it to an account.</td></tr><tr><td>-b <i>base_dir</i></td><td>The default base directory for the system if -d <i>dir</i> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the -m option is not used, <i>base_dir</i> must exist.</td></tr><tr><td>-c <i>comment</i></td><td>Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's /etc/passwd entry.</td></tr></table>	-A <i>authorization</i>	One or more comma separated authorizations defined in <i>auth_attr</i> (4). Only a user or role who has <i>grant</i> rights to the authorization can assign it to an account.	-b <i>base_dir</i>	The default base directory for the system if -d <i>dir</i> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the -m option is not used, <i>base_dir</i> must exist.	-c <i>comment</i>	Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's /etc/passwd entry.
-A <i>authorization</i>	One or more comma separated authorizations defined in <i>auth_attr</i> (4). Only a user or role who has <i>grant</i> rights to the authorization can assign it to an account.						
-b <i>base_dir</i>	The default base directory for the system if -d <i>dir</i> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the -m option is not used, <i>base_dir</i> must exist.						
-c <i>comment</i>	Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's /etc/passwd entry.						

-d <i>dir</i>	The home directory of the new user. It defaults to <i>base_dir/account_name</i> , where <i>base_dir</i> is the base directory for new login home directories and <i>account_name</i> is the new login name.																						
-D	<p>Display the default values for <i>group</i>, <i>base_dir</i>, <i>skel_dir</i>, <i>shell</i>, <i>inactive</i>, <i>expire</i>, <i>proj</i> and <i>projname</i>. When used with the <i>-g</i>, <i>-b</i>, <i>-f</i>, <i>-e</i>, <i>-A</i>, <i>-P</i>, <i>-p</i>, or <i>-R</i> options, the <i>-D</i> option sets the default values for the specified fields. The default values are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><i>group</i></td> <td>other (GID of 1)</td> </tr> <tr> <td><i>base_dir</i></td> <td>/home</td> </tr> <tr> <td><i>skel_dir</i></td> <td>/etc/skel</td> </tr> <tr> <td><i>shell</i></td> <td>/bin/sh</td> </tr> <tr> <td><i>inactive</i></td> <td>0</td> </tr> <tr> <td><i>expire</i></td> <td>null</td> </tr> <tr> <td><i>auths</i></td> <td>null</td> </tr> <tr> <td><i>profiles</i></td> <td>null</td> </tr> <tr> <td><i>proj</i></td> <td>3</td> </tr> <tr> <td><i>projname</i></td> <td>default</td> </tr> <tr> <td><i>roles</i></td> <td>null</td> </tr> </table>	<i>group</i>	other (GID of 1)	<i>base_dir</i>	/home	<i>skel_dir</i>	/etc/skel	<i>shell</i>	/bin/sh	<i>inactive</i>	0	<i>expire</i>	null	<i>auths</i>	null	<i>profiles</i>	null	<i>proj</i>	3	<i>projname</i>	default	<i>roles</i>	null
<i>group</i>	other (GID of 1)																						
<i>base_dir</i>	/home																						
<i>skel_dir</i>	/etc/skel																						
<i>shell</i>	/bin/sh																						
<i>inactive</i>	0																						
<i>expire</i>	null																						
<i>auths</i>	null																						
<i>profiles</i>	null																						
<i>proj</i>	3																						
<i>projname</i>	default																						
<i>roles</i>	null																						
-e <i>expire</i>	<p>Specify the expiration date for a login. After this date, no user will be able to access this login. The <i>expire</i> option argument is a date entered using one of the date formats included in the template file <i>/etc/datemsk</i>. See <i>getdate(3C)</i>.</p> <p>If the date format that you choose includes spaces, it must be quoted. For example, you can enter <i>10/6/90</i> or <i>"October 6, 1990"</i>. A null value (<i>" "</i>) defeats the status of the expired date. This option is useful for creating temporary logins.</p>																						
-f <i>inactive</i>	The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.																						
-g <i>group</i>	An existing group's integer ID or character-string name. Without the <i>-D</i> option, it defines the new user's primary group membership and defaults to the default																						

useradd(1M)

	<p>group. You can reset this default value by invoking <code>useradd -D -g group</code>.</p>
<code>-G group</code>	<p>An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between <i>group</i> with the <code>-g</code> and <code>-G</code> options are ignored. No more than <code>NGROUPS_MAX</code> groups can be specified.</p>
<code>-k skel_dir</code>	<p>A directory that contains skeleton information (such as <code>.profile</code>) that can be copied into a new user's home directory. This directory must already exist. The system provides the <code>/etc/skel</code> directory that can be used for this purpose.</p>
<code>-m</code>	<p>Create the new user's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by <i>group</i>, where <i>group</i> is the user's primary group.</p>
<code>-o</code>	<p>This option allows a UID to be duplicated (non-unique).</p>
<code>-P profile</code>	<p>One or more comma-separated execution profiles defined in <code>prof_attr(4)</code>.</p>
<code>-p projname</code>	<p>Name of the project with which the added user is associated. See the <i>projname</i> field as defined in <code>project(4)</code>.</p>
<code>-R role</code>	<p>One or more comma-separated execution profiles defined in <code>user_attr(4)</code>. Roles cannot be assigned to other roles.</p>
<code>-s shell</code>	<p>Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use <code>/bin/sh</code> as the default. The value of <i>shell</i> must be a valid executable file.</p>
<code>-u uid</code>	<p>The UID of the new user. This UID must be a non-negative decimal integer below <code>MAXUID</code> as defined in <code><sys/param.h></code>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved for possible use in future applications.)</p>

FILES `/etc/datenssk`
`/etc/passwd`

/etc/shadow
 /etc/group
 /etc/skel
 /usr/include/limits.h
 /etc/user_attr

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), passwd(4), prof_attr(4), project(4), user_attr(4), attributes(5)

DIAGNOSTICS In case of an error, useradd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the *uid* specified with the *-u* option is not unique:

UX: useradd: ERROR: uid *uid* is already in use. Choose another.

The following indicates that the *group* specified with the *-g* option is already in use:

UX: useradd: ERROR: group *group* does not exist. Choose another.

The following indicates that the *uid* specified with the *-u* option is in the range of reserved UIDs (from 0-99):

UX: useradd: WARNING: uid *uid* is reserved.

The following indicates that the *uid* specified with the *-u* option exceeds MAXUID as defined in <sys/param.h>:

UX: useradd: ERROR: uid *uid* is too big. Choose another.

The following indicates that the */etc/passwd* or */etc/shadow* files do not exist:

UX: useradd: ERROR: Cannot update system files - login cannot be created.

NOTES The useradd utility adds definitions to only the local */etc/group*, *etc/passwd*, */etc/passwd*, */etc/shadow*, */etc/project*, and */etc/user_attr* files. If a network name service such as NIS or NIS+ is being used to supplement the local

useradd(1M)

/etc/passwd file with additional entries, useradd cannot change information supplied by the network name service. However useradd will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.

NAME	userdel – delete a user’s login from the system				
SYNOPSIS	userdel [-r] <i>login</i>				
DESCRIPTION	The <code>userdel</code> utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.				
OPTIONS	The following options are supported: -r Remove the user’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.				
OPERANDS	The following operands are supported: <i>login</i> An existing login name to be deleted.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 Invalid command syntax. A usage message for the <code>userdel</code> command is displayed. 6 The account to be removed does not exist. 8 The account to be removed is in use. 10 Cannot update the <code>/etc/group</code> or <code>/etc/user_attr</code> file but the login is removed from the <code>/etc/passwd</code> file. 12 Cannot remove or otherwise modify the home directory.				
FILES	<code>/etc/passwd</code> system password file <code>/etc/shadow</code> system file contain users’ encrypted passwords and related information <code>/etc/group</code> system file containing group definitions <code>/etc/user_attr</code> system file containing additional user attributes				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>auths(1)</code> , <code>passwd(1)</code> , <code>profiles(1)</code> , <code>roles(1)</code> , <code>users(1B)</code> , <code>groupadd(1M)</code> , <code>groupdel(1M)</code> , <code>groupmod(1M)</code> , <code>logins(1M)</code> , <code>roleadd(1M)</code> , <code>rolemod(1M)</code> , <code>useradd(1M)</code> , <code>userdel(1M)</code> , <code>usermod(1M)</code> , <code>passwd(4)</code> , <code>prof_attr(4)</code> , <code>user_attr(4)</code> , <code>attributes(5)</code>				

userdel(1M)

NOTES | The `userdel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `userdel` cannot change information supplied by the network name service.

NAME	usermod – modify a user’s login information on the system
SYNOPSIS	usermod [-u <i>uid</i> [-o]] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i> ...]] [-d <i>dir</i> [-m]] [-s <i>shell</i>] [-c <i>comment</i>] [-l <i>new_name</i>] [-f <i>inactive</i>] [-e <i>expire</i>] [-A <i>authorization</i> [, <i>authorization</i>]] [-P <i>profile</i> [, <i>profile</i>]] [-R <i>role</i> [, <i>role</i>]] <i>login</i>
DESCRIPTION	<p>The usermod utility modifies a user’s login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -A <i>authorization</i> One or more comma separated authorizations as defined in <code>auth_attr(4)</code>. Only a user or role who has grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting. -c <i>comment</i> Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry. -d <i>dir</i> Specify the new home directory of the user. It defaults to <code>base_dir/login</code>, where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login. -e <i>expire</i> Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>. For example, you may enter <code>10/6/90</code> or <code>October 6, 1990</code>. A value of <code>''</code> defeats the status of the expired date. -f <i>inactive</i> Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status. -g <i>group</i> Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.

usermod(1M)

<code>-G group</code>	Specify an existing group's integer "ID" ", " or character string name. It redefines the user's supplementary group membership. Duplicates between <i>group</i> with the <code>-g</code> and <code>-G</code> options are ignored. No more than <code>NGROUPS_UMAX</code> groups may be specified as defined in <code><param.h></code> .
<code>-l new_logname</code>	Specify the new login name for the user. The <i>new_logname</i> argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The <i>new_logname</i> argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).
<code>-m</code>	Move the user's home directory to the new directory specified with the <code>-d</code> option. If the directory already exists, it must have permissions read/write/execute by <i>group</i> , where <i>group</i> is the user's primary group.
<code>-o</code>	This option allows the specified UID to be duplicated (non-unique).
<code>-P profile</code>	One or more comma-separated execution profiles defined in <code>auth_attr(4)</code> . This replaces any existing profile setting.
<code>-R role</code>	One or more comma-separated execution profiles defined in <code>auth_attr(4)</code> . This replaces any existing role setting.
<code>-s shell</code>	Specify the full pathname of the program that is used as the user's shell on login. The value of <i>shell</i> must be a valid executable file.
<code>-u uid</code>	Specify a new UID for the user. It must be a non-negative decimal integer less than <code>MAXUID</code> as defined in <code><param.h></code> . The UID associated with the user's home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using <code>chown(1M)</code> .

OPERANDS The following operands are supported:

`login` An existing login name to be modified.

EXIT STATUS In case of an error, `usermod` prints an error message and exits with one of the following values:

- 2 The command syntax was invalid. A usage message for the `usermod` command is displayed.
- 3 An invalid argument was provided to an option.
- 4 The *uid* given with the `-u` option is already in use.
- 5 The password files contain an error. `pwconv(1M)` can be used to correct possible errors. See `passwd(4)`.
- 6 The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8 The login to be modified is in use.
- 9 The *new_logname* is already in use.
- 10 Cannot update the `/etc/group` or `/etc/user_attr` file. Other update requests will be implemented.
- 11 Insufficient space to move the home directory (`-m` option). Other update requests will be implemented.
- 12 Unable to complete the move of the home directory to the new home directory.

FILES

<code>/etc/group</code>	system file containing group definitions
<code>/etc/datemsk</code>	system file of date formats
<code>/etc/passwd</code>	system password file
<code>/etc/shadow</code>	system file containing users' encrypted passwords and related information
<code>/etc/usr_attr</code>	system file containing additional user and role attributes

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `passwd(1)`, `users(1B)`, `chown(1M)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `pwconv(1M)`, `roleadd(1M)`, `roledel(1M)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `attributes(5)`

usermod(1M)

NOTES | The `usermod` utility modifies `passwd` definitions only in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `usermod` cannot change information supplied by the network nameservice. However `usermod` will verify the uniqueness of user name and user ID against the external nameservice.

The `usermod` utility uses the `/etc/datemsk` file, available with SUNWaccr, for date formatting.

NAME	utmpd – utmp and utmpx monitoring daemon						
SYNOPSIS	utmpd [-debug]						
DESCRIPTION	<p>The utmpd daemon monitors /var/adm/utmp and /var/adm/utmpx files. See utmp(4) and utmpx(4).</p> <p>utmpd receives requests from pututline(3C) and pututxline(3C) by way of a named pipe. It maintains a table of processes and uses poll(2) on /proc files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmp entry from /var/adm/utmp and /var/adm/utmpx. If the process' utmp entry has not been removed, utmpd removes the entry. By periodically scanning the /var/adm/utmp and /var/adm/utmpx files, utmpd also monitors processes that are not in its table.</p>						
OPTIONS	-debug Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.						
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>

uuccheck(1M)

NAME	uuccheck – check the uucp directories and permissions file				
SYNOPSIS	<code>/usr/lib/uucp/uuccheck [-v] [-x <i>debug-level</i>]</code>				
DESCRIPTION	<p>uuccheck checks for the presence of the uucp system required files and directories. uuccheck also does error checking of the <code>Permissions</code> file (<code>/etc/uucp/Permissions</code>).</p> <p>uuccheck is executed during package installation. uuccheck can only be used by the super-user or uucp.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-v</code> Give a detailed (verbose) explanation of how the uucp programs will interpret the <code>Permissions</code> file.<code>-x <i>debug-level</i></code> Produce debugging output on the standard output. <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.				
FILES	<ul style="list-style-type: none"><code>/etc/uucp/Devices</code><code>/etc/uucp/Limits</code><code>/etc/uucp/Permissions</code><code>/etc/uucp/Systems</code><code>/var/spool/locks/*</code><code>/var/spool/uucp/*</code><code>/var/spool/uucppublic/*</code>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWbnuu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWbnuu				
SEE ALSO	<code>uucp(1C)</code> , <code>uustat(1C)</code> , <code>uux(1C)</code> , <code>uucico(1M)</code> , <code>uusched(1M)</code> , <code>attributes(5)</code>				
BUGS	The program does not check file/directory modes or some errors in the <code>Permissions</code> file such as duplicate login or machine name.				

NAME	uucico – file transport program for the uucp system
SYNOPSIS	<code>/usr/lib/uucp/uucico [-f] [-c <i>type</i>] [-d <i>spool-directory</i>] [-i <i>interface</i>] [-r <i>role-number</i>] [-s <i>system-name</i>] [-x <i>debug-level</i>]</code>
DESCRIPTION	uucico is the file transport program for uucp work file transfers.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -f This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the <code>/etc/uucp/Limits</code> file. -c <i>type</i> The first field in the <code>Devices</code> file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network. -d <i>spool-directory</i> This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is <code>/var/spool/uucp</code>. -i <i>interface</i> This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write). -r <i>role-number</i> The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode. -s <i>system-name</i> The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the <code>Systems</code> file. -x <i>debug-level</i> Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the <code>usched</code> scheduler, for debugging purposes, and can be started manually. For example, the shell <code>Uutry</code> starts uucico with debugging turned on. The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information.

uucico(1M)

FILES /etc/uucp/Devconfig
/etc/uucp/Devices
/etc/uucp/Limits
/etc/uucp/Permissions
/etc/uucp/Sysfiles
/etc/uucp/Systems

NAME	uucleanup – uucp spool directory clean-up
SYNOPSIS	<code>/usr/lib/uucp/uucleanup</code> [-Ctime] [-Dtime] [-mstring] [-otime] [-ssystem] [-Wtime] [-xdebug-level] [-Xtime]
DESCRIPTION	<p>uucleanup will scan the spool directories for old files and take appropriate action to remove them in a useful way:</p> <ul style="list-style-type: none"> ■ Inform the requester of send/receive requests for systems that can not be reached. ■ Return undeliverable mail to the sender. ■ Deliver rnews files addressed to the local system. ■ Remove all other files. <p>In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: uucleanup will process as if all option times were specified to the default values unless time is specifically set.</p> <p>This program is typically started by the shell <code>uudemon.cleanup</code>, which should be started by <code>cron(1M)</code>.</p>
OPTIONS	<p>-Ctime Remove any C. files greater or equal to time days old and send appropriate information to the requester (default 7 days).</p> <p>-Dtime Remove any D. files greater or equal to time days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).</p> <p>-mstring Include string in the warning message generated by the -w option. The default line is "See your local administrator to locate the problem".</p> <p>-otime Delete other files whose age is more than time days (default 2 days).</p> <p>-ssystem Execute for system spool directory only.</p> <p>-Wtime Any C. files equal to time days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the <i>JOBID</i>, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).</p> <p>-xdebug-level Produce debugging output on standard output. debug-level is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)</p> <p>-Xtime Any X. files greater or equal to time days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by</p>

uucleanup(1M)

D. processing (default 2 days).

FILES /usr/lib/uucp directory with commands used by uucleanup internally

Uutry(1M)

NAME	Uutry, uutry – attempt to contact remote system with debugging on				
SYNOPSIS	<code>/usr/lib/uucp/Uutry [-r] [-c <i>type</i>] [-x <i>debug-level</i>] <i>system-name</i></code>				
DESCRIPTION	Uutry is a shell script that is used to invoke uucico(1M) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file <code>/tmp/system-name</code> .				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-r</code> This option overrides the retry time that is set in file <code>/var/uucp/.Status/system-name</code>.<code>-c <i>type</i></code> The first field in the Devices file is the "Type" field. The <code>-c</code> option forces uucico to use only entries in the "Type" field that match the user-specified type. NAME	uuxqt – execute remote command requests				
SYNOPSIS	<code>/usr/lib/uucp/uuxqt [-s <i>system</i>] [-x <i>debug-level</i>]</code>				
DESCRIPTION	<p>uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.</p> <p>There are two environment variables that are set before the uuxqt command is executed:</p> <ul style="list-style-type: none"> ■ UU_MACHINE is the machine that sent the job (the previous one). ■ UU_USER is the user that sent the job. <p>These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.</p>				
OPTIONS	<p>The following options are supported:</p> <p><code>-s <i>system</i></code> Specifies the remote <i>system</i> name.</p> <p><code>-x <i>debug-level</i></code> <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.</p>

vmstat(1M)

NAME	vmstat – report virtual memory statistics
SYNOPSIS	vmstat [-cipsS] [disks] [interval [count]]
DESCRIPTION	<p>vmstat reports virtual memory statistics regarding process, virtual memory, disk, trap, and CPU activity.</p> <p>On MP systems, vmstat averages the number of CPUs into the output. For per-process statistics, see mpstat(1M).</p> <p>vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M).</p> <p>Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.</p> <p>During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. vmstat will report this as <<State change>>.</p> <p>See <i>Solaris Transition Guide</i> for device naming conventions for disks.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Report cache flushing statistics. By default, report the total number of each kind of cache flushed since boot time. The types are: user, context, region, segment, page, and partial-page.-i Report the number of interrupts per device. <i>count</i> and <i>interval</i> does not apply to the -i option.-p Report paging activity in details. This option will display the following, respectively:<ul style="list-style-type: none">epi Executable page-ins.epo Executable page-outs.epf Executable page-frees.api Anonymous page-ins.apo Anonymous page-outs.apf Anonymous page-frees.fpi File system page-ins.fpo File system page-outs.fpf File system page-frees.-s Display the total number of various system events since boot. <i>count</i> and <i>interval</i> does not apply to the -s option.

-S Report on swapping rather than paging activity. This option will change two fields in `vmstat`'s "paging" display: rather than the "re" and "mf" fields, `vmstat` will report "si" (swap-ins) and "so" (swap-outs).

OPERANDS The following operands are supported:

count Specifies the number of times that the statistics are repeated. *count* does not apply to the `-i` and `-s` options.

disks Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are `id`, `sd`, `xd`, or `xy`, followed by a number (for example, `sd2`, `xd0`, and so forth).

interval Specifies the last number of seconds over which `vmstat` summarizes activity. This number of seconds repeats forever. *interval* does not apply to the `-i` and `-s` options.

EXAMPLES **EXAMPLE 1** Using `vmstat`

The following command displays a summary of what the system is doing every five seconds.

```
example% vmstat 5
procs memory          page          disk          faults          cpu
r b w swap  free re mf pi p fr de sr s0 s1 s2 s3  in sy cs us sy id
0 0 0 11456 4120 1  41 19 1  3  0  2  0  4  0  0  48 112 130  4 14 82
0 0 1 10132 4280 0   4 44 0  0  0  0  0 23  0  0 211 230 144  3 35 62
0 0 1 10132 4616 0   0 20 0  0  0  0  0 19  0  0 150 172 146  3 33 64
0 0 1 10132 5292 0   0  9 0  0  0  0  0 21  0  0 165 105 130  1 21 78
1 1 1 10132 5496 0   0  5 0  0  0  0  0 23  0  0 183  92 134  1 20 79
1 0 1 10132 5564 0   0 25 0  0  0  0  0 18  0  0 131 231 116  4 34 62
1 0 1 10124 5412 0   0 37 0  0  0  0  0 22  0  0 166 179 118  1 33 67
1 0 1 10124 5236 0   0 24 0  0  0  0  0 14  0  0 109 243 113  4 56 39
^Cexample%
```

The fields of `vmstat`'s display are

procs Report the number of processes in each of the three following states:

- `r` in run queue
- `b` blocked for resources I/O, paging, and so forth
- `w` swapped

memory Report on usage of virtual and real memory.

- `swap` amount of swap space currently available (Kbytes)
- `free` size of the free list (Kbytes)

page Report information about page faults and paging activity. The information on each of the following activities is given in units per second.

vmstat(1M)

EXAMPLE 1 Using vmstat (Continued)

re	page reclaims — but see the -S option for how this field is modified.
mf	minor faults — but see the -S option for how this field is modified.
pi	kilobytes paged in
po	kilobytes paged out
fr	kilobytes freed
de	anticipated short-term memory shortfall (Kbytes)
sr	pages scanned by clock algorithm
disk	Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (s = SCSI, i = IPI, and so forth); the number is the logical unit number.
faults	Report the trap/interrupt rates (per second).
in	(non clock) device interrupts
sy	system calls
cs	CPU context switches
cpu	Give a breakdown of percentage usage of CPU time. On MP systems, this is an average across all processors.
us	user time
sy	system time
id	idle time

vmstat(1M)

NOTES The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

volcopy(1M)

NAME	volcopy – make an image copy of file system
SYNOPSIS	volcopy [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>operands</i>
DESCRIPTION	volcopy makes a literal copy of the file system. This command may not be supported for all <i>FSTypes</i> .
OPTIONS	<p>The following options are supported:</p> <p>-F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <code>/etc/vfstab</code> by matching the <i>operands</i> with an entry in the table. Otherwise, the default file system type specified in <code>/etc/default/fs</code> will be used.</p> <p>-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <code>/etc/vfstab</code>. This option should be used to verify and validate the command line.</p> <p><i>generic_options</i> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available:</p> <ul style="list-style-type: none">-a Require the operator to respond “yes” or “no” instead of simply waiting ten seconds before the copy is made.-s (Default) Invoke the DEL if wrong verification sequence. <p>-o <i>FSType-specific_options</i> Specify <i>FSType</i>-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>operands</i> generally include the device and volume names and are file system specific. A detailed description of the <i>operands</i> can be found on the <i>FSType</i>-specific man pages of <code>volcopy</code>.</p>
EXIT STATUS	The following exit values are returned:

0 Successful file system copy

1 An error has occurred.

FILES /etc/vfstab list of default parameters for each file system
 /etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs.
 LOCAL: The default partition for a command if no *FSType* is specified.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO labelit(1M), vfstab(4), attributes(5) Manual pages for the *FSType*-specific modules of volcopy.

volcopy_ufs(1M)

NAME	volcopy_ufs – make an image copy of a ufs file system				
SYNOPSIS	volcopy [-F ufs] [<i>generic_options</i>] <i>fsname srcdevice volname1 destdevice volname2</i>				
DESCRIPTION	volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.				
OPTIONS	The following option is supported: <i>generic_options</i> options supported by the generic volcopy command. See volcopy(1M).				
OPERANDS	The following operands are supported: <i>fsname</i> represents the mount point (for example, root, u1, etc.) of the file system being copied. <i>srcdevice</i> or <i>destdevice</i> the disk partition specified using the raw device (for example, /dev/rdisk/c1d0s8, /dev/rdisk/c1d1s8, etc.). <i>srcdevice</i> and <i>volname1</i> the device and physical volume from which the copy of the file system is being extracted. <i>destdevice</i> and <i>volname2</i> the target device and physical volume. <i>fsname</i> and <i>volname</i> are limited to six or fewer characters and recorded in the superblock. <i>volname</i> may be '-' to use the existing volume name.				
EXIT STATUS	The following exit values are returned: 0 Successful file system copy. non-zero An error has occurred.				
FILES	/var/adm/filesave.log a record of file systems/volumes copied				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	cpio(1), dd(1M), labelit(1M), volcopy(1M), fs_ufs(4), attributes(5)				
NOTES	volcopy does not support copying to tape devices. Use dd(1M) for copying to and from tape devices.				

NAME	vold – Volume Management daemon to manage CD-ROM and floppy, ZIP/JAZ and DVD-ROM devices
SYNOPSIS	<code>/usr/sbin/vold [-n] [-t] [-v] [-f <i>config-file</i>] [-l <i>log-file</i>] [-d <i>root-dir</i>] [-L <i>debug-level</i>]</code>
DESCRIPTION	<p>The Volume Management daemon, vold, creates and maintains a file system image rooted at <i>root-dir</i> that contains symbolic names for floppies, CD-ROMs and other removable devices. The default <i>root-dir</i> is set to /vol if no directory is specified by the -d option.</p> <p>vold reads the /etc/vold.conf configuration file upon startup. If the configuration file is modified later, vold must be told to reread the /etc/vold.conf file. Do this by entering</p> <pre>example# kill -HUP vold_pid</pre> <p>To tell vold to clean up and exit, the SIGTERM signal is used:</p> <pre>example# kill -TERM vold_pid</pre> <p>where vold_pid is the process ID of vold.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -n Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE. -t Dump NFS trace information to the log file. The default setting is FALSE. -v Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file). -d<i>root-dir</i> Specify an alternate root directory. The default location is /vol. Setting this will also cause other Volume Management utilities to use this as the default root directory. -f <i>config-file</i> Specify an alternate configuration file. The default file is /etc/vold.conf. -l <i>log-file</i> Specify an alternate log file. The default log file is /var/adm/vold.log. -L <i>debug-level</i> Change the level (verbosity) of debug messages sent to the log file. The range is 0 to 99 where 0 is nothing and 99 is everything. The default level is 0.
ENVIRONMENT VARIABLES	vold sets the following environment variables to aid programs which are called when events such as insert, notify, and eject occur:

vold(1M)

VOLUME_ACTION	Event that caused this program to be executed.
VOLUME_PATH	Pathname of the matched <i>regex</i> from the <code>vold.conf</code> file.
VOLUME_DEVICE	Device (in <code>/vol/dev</code>) that applies to the media.
VOLUME_NAME	Name of the volume in question.
VOLUME_USER	User ID of the user causing the event to occur.
VOLUME_SYMNAME	Symbolic name of a device containing the volume.
VOLUME_MEDIATYPE	Name of the type of media (CD-ROM, floppy or rmdisk)

FILES

<code>/etc/vold.conf</code>	Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
<code>/usr/lib/vold/*.so.1</code>	Shared objects called by Volume Management daemon when certain actions occur.
<code>/var/adm/vold.log</code>	the default log file location (see the <code>-l</code> option for a description).
<code>/vol</code>	the default Volume Management root directory.

System Administration Guide, Volume 1

NAME	wall – write to all users				
SYNOPSIS	<code>/usr/sbin/wall [-a] [-g <i>grpname</i>] [<i>filename</i>]</code>				
DESCRIPTION	<p>wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:</p> <pre>Broadcast Message from . . .</pre> <p>If <i>filename</i> is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, <code>-a</code> will send the message even to such pseudo-terminals.</p> <p>It is used to warn all users, typically prior to shutting down the system.</p> <p>The sender must be superuser to override any protections the users may have invoked. See <code>mesg(1)</code>.</p> <p>wall runs <code>setgid()</code> to the group ID <code>tty</code>, in order to have write permissions on other user's terminals. See <code>setuid(2)</code>.</p> <p>wall will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a " ^ " followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, <code>'\003'</code> is displayed as <code>'^C'</code> and <code>'\372'</code> as <code>'M-z'</code>.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-a</code> broadcast message to the console and pseudo-terminals. <code>-g <i>grpname</i></code> broadcast to a specified group only. 				
ENVIRONMENT VARIABLES	<p>If the <code>LC_*</code> variables (<code>LC_CTYPE</code>, <code>LC_TIME</code>, <code>LC_COLLATE</code>, <code>LC_NUMERIC</code>, and <code>LC_MONETARY</code>) are not set in the environment, the operational behavior of wall for each corresponding locale category is determined by the value of the <code>LANG</code> environment variable. See <code>environ(5)</code>. If <code>LC_ALL</code> is set, its contents are used to override both the <code>LANG</code> and the other <code>LC_*</code> variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how wall behaves.</p>

wall(1M)

NOTES | wall displays "Cannot send to . . ." when the open on a user's tty file fails.

NAME	wbemadmin – start Sun WBEM User Manager				
SYNOPSIS	<code>/usr/sadm/bin/wbemadmin</code>				
DESCRIPTION	<p>The <code>wbemadmin</code> utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.</p> <p>The <code>wbemadmin</code> utility allows you to perform the following tasks:</p> <table border="0"> <tr> <td style="vertical-align: top;">Manage user access rights</td> <td>Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.</td> </tr> <tr> <td style="vertical-align: top;">Manage namespace access rights</td> <td>Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.</td> </tr> </table> <p>The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the <code>root\security</code> namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.</p> <p>Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.</p> <p>All programming operations are performed within a namespace. Two namespaces are created by default during installation:</p> <ul style="list-style-type: none"> ■ <code>root\cimv2</code> — Contains the default CIM classes that represent objects on your system. ■ <code>root\security</code> — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces. <p>When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.</p> <p>When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.</p>	Manage user access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.	Manage namespace access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.
Manage user access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.				
Manage namespace access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.				

wbemadmin(1M)

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- **Read Only** — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- **Read/Write** — Allows full read, write, and delete access to all CIM classes and instances.
- **Write** — Allows write and delete, but not read access to all CIM classes and instances.
- **None** — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the `wbemadmin` dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The `wbemadmin` security administration tool updates the following Java classes in the `root\security` namespace:

- `Solaris_UserAcl` — Updated when access rights are granted or changed for a user.
- `Solaris_namespaceAcl` — Updated when access rights are granted or changed for a namespace.

USAGE The `wbemadmin` utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

EXIT STATUS The `wbemadmin` utility terminates with exit status 0.

WARNING The `root\security` namespace stores access privileges. If you grant other users access to the `root\security` namespace, those users can grant themselves or other users rights to all other namespaces.

wbemconfig(1M)

NAME	wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format				
SYNOPSIS	<code>/usr/sadm/lib/wbem/wbemconfig convert</code>				
DESCRIPTION	<p>A Reliable Log directory is created that contains the converted data. This directory is named <code>/var/sadm/wbem/logr</code>.</p> <p>The <code>convert</code> argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the <code>init.wbem stop</code> command. Otherwise your data may be corrupted.</p> <p>This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the <code>mofcomp</code> command on the MOF files containing the class definitions.</p> <p>Because the <code>wbemconfig convert</code> command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the <code>wbemconfig convert</code> command is completed, you can change to any version of the JVM you want.</p> <p>To see what version of the JVM you are running, issue the <code>java -version</code> command.</p>				
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>convert</code></td><td>Convert a JavaSpaces datastore to the newer Reliable Log datastore format.</td></tr></table>	<code>convert</code>	Convert a JavaSpaces datastore to the newer Reliable Log datastore format.		
<code>convert</code>	Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

NAME	wbemlogviewer – start WBEM Log Viewer								
SYNOPSIS	<code>/usr/sadm/bin/wbemlogviewer</code>								
DESCRIPTION	<p>The <code>wbemlogviewer</code> utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the <code>root\cimv2</code> namespace to view and maintain log files. Namespaces are described in <code>wbemadmin(1M)</code>.</p> <p>Log events can have three severity levels.</p> <ul style="list-style-type: none"> ■ Errors ■ Warnings ■ Informational <p>The WBEM log file is created in the <code>/var/sadm/wbem/log</code> directory, with the name <code>wbem_log</code>. The first time the log file is backed up, it is renamed <code>wbem_log.1</code>, and a new <code>wbem_log</code> file is created. Each succeeding time the <code>wbem_log</code> file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed. Older backup files have higher file extension numbers than more recent backup files.</p> <p>The log file is renamed with a <code>.1</code> file extension and saved when one of the following two conditions occur:</p> <ul style="list-style-type: none"> ■ The current file reaches the file size limit specified in the WBEM Services properties file, <code>/var/sadm/wbem/WbemServices.properties</code>. ■ A WBEM client application uses the <code>clearLog()</code> method in the <code>Solaris_LogService</code> class to clear the current log file. <p>The WBEM Services properties file <code>/var/sadm/wbem/WbemServices.properties</code> is modified when you change the properties of log files.</p> <p>Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.</p>								
USAGE	<p>The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.</p> <p>The WBEM Log Viewer allows you to perform the following tasks:</p> <table border="0"> <tr> <td>View the logs</td> <td></td> </tr> <tr> <td>Set properties of log files</td> <td>Click Action->Log File Settings to specify log file parameters and the log file directory.</td> </tr> <tr> <td>Back up a log file</td> <td>Click Action->Back Up Now to back up and close the current log file and start a new log file.</td> </tr> <tr> <td>Delete an old log file</td> <td>Click Action->Open Log File to open a backed-up log file. To delete a backed-up log file, open it and then</td> </tr> </table>	View the logs		Set properties of log files	Click Action->Log File Settings to specify log file parameters and the log file directory.	Back up a log file	Click Action->Back Up Now to back up and close the current log file and start a new log file.	Delete an old log file	Click Action->Open Log File to open a backed-up log file. To delete a backed-up log file, open it and then
View the logs									
Set properties of log files	Click Action->Log File Settings to specify log file parameters and the log file directory.								
Back up a log file	Click Action->Back Up Now to back up and close the current log file and start a new log file.								
Delete an old log file	Click Action->Open Log File to open a backed-up log file. To delete a backed-up log file, open it and then								

wbemlogviewer(1M)

click Action->Delete Log File. You can only delete backed-up log files.

View log record details

Double-click a log entry to display its details.

Sort the logs

Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

EXIT STATUS The `wbemlogviewer` utility terminates with exit status 0.

NAME	whodo – who is doing what
SYNOPSIS	<code>/usr/sbin/whodo [-h] [-l] [user]</code>
DESCRIPTION	<p>whodo produces formatted and dated output from information in the <code>/var/adm/utmpx</code>, <code>/tmp/ps_data</code>, and <code>/proc/pid</code> files.</p> <p>The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.</p> <p>If <i>user</i> is specified, output is restricted to all sessions pertaining to that user.</p>
OPTIONS	<p><code>-h</code> Suppress the heading.</p> <p><code>-l</code> Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in <i>hours:minutes</i>), the idle time — that is, the time since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.</p>
EXAMPLES	<p>EXAMPLE 1 An example of the whodo command.</p> <p>The command:</p> <pre>example% whodo</pre> <p>produces a display like this:</p> <pre>Tue Mar 12 15:48:03 1985 bailey tty09 mcn 8:51 tty09 28158 0:29 sh tty52 bdr 15:23 tty52 21688 0:05 sh tty52 22788 0:01 whodo tty52 22017 0:03 vi tty52 22549 0:01 sh xt162 lee 10:20 tty08 6748 0:01 layers xt162 6751 0:01 sh xt163 6761 0:05 sh tty08 6536 0:05 sh</pre>
ENVIRONMENT VARIABLES	<p>If any of the <code>LC_*</code> variables (<code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, <code>LC_TIME</code>, <code>LC_COLLATE</code>, <code>LC_NUMERIC</code>, and <code>LC_MONETARY</code>) (see <code>environ(5)</code>) are not set in the environment, the operational behavior of <code>tar(1)</code> for each corresponding locale category is determined by the value of the <code>LANG</code> environment variable. If <code>LC_ALL</code> is</p>

whodo(1M)

set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `tar` behaves.

`LC_CTYPE` Determines how `tar` handles characters. When `LC_CTYPE` is set to a valid value, `tar` can display and handle text and filenames containing valid characters for that locale. `tar` can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `tar` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_MESSAGES` Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

`LC_TIME` Determines how `tar` handles date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

FILES `/etc/passwd` system password file
`/tmp/ps_data`
`/var/adm/utmpx` user access and administration information
`/proc/pid`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `ps(1)`, `tar(1)`, `who(1)`, `attributes(5)`, `environ(5)`

DIAGNOSTICS If the PROC driver is not installed or configured or if `/proc` is not mounted, a message to that effect is issued and `whodo` will fail.

NAME	wracct – write extended accounting records for active processes and tasks
SYNOPSIS	<code>/usr/sbin/wracct [-trecord_type] i id_list {task process}</code>
DESCRIPTION	The wracct utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a record_type option is also supported, allowing the administrator to request the writing of a partial record, which leaves the current task usage unchanged, or an interval record, which resets the task usage to zero for that system task, with respect to the extended accounting subsystem. If interval records are used, the total task usage is the sum of all interval records and the final record written at the task's completion. If partial records are used, the completion record reflects the total resource usage.
OPTIONS	<p>The following options are supported:</p> <p><code>-i id_list</code> Select the IDs of the tasks or processes to write records for. Specify <i>id_list</i> as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.</p> <p><code>-t record_type</code> Select type of record to write for the selected task or process. For tasks, <i>record_type</i> can be <code>partial</code> or <code>interval</code>. <code>partial</code> is the the default type, and the only type available for process records.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>process</i> Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.</p> <p><i>task</i> Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.</p>
EXAMPLES	<p>EXAMPLE 1 Writing a partial record</p> <p>Write a partial record for all active <code>sendmail</code> processes.</p> <pre># /usr/sbin/wracct -i "`pgrep sendmail`" process</pre> <p>EXAMPLE 2 Writing an interval record</p> <p>Write an interval record for the task with ID 182.</p> <pre># /usr/sbin/wracct -t interval -i 182 task</pre>
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p> <p>2 Invalid command line options were specified.</p>

wracct(1M)

3 Pertinent components of extended accounting facility are not active.

FILES /var/adm/exacct/task

/var/adm/exacct/proc Extended accounting data files.

NAME	wrsmconf – manage WCI RSM controller configurations
SYNOPSIS	<pre> /opt/SUNWwrsm/bin/wrsmconf create -c controller_id -f config_file wrsmconf initial -f config_file [-c controller_id] wrsmconf remove [-c controller_id] wrsmconf topology [-c controller_id] wrsmconf dump -c controller_id -f config_file </pre>
DESCRIPTION	wrsmconf provides a means to create, install, retrieve, and remove configurations for WCI remote shared memory (RSM) controllers.
OPTIONS	<p>The following options are supported:</p> <p>create -c controller_id -f config_file Create a set of per-node configurations for the specified controller and store them to the file <i>config_file</i>. The created file contains a per-node configuration for each node specified in the input for the specified controller. The file has a checksum on it and cannot be modified directly. This file can be used in a <code>wrsmconf initial</code> call on each node to install the node's configuration into the local driver.</p> <p>A list of nodes and WCI devices connected to those nodes is read from standard input. For each connected pair of links, specify the nodename (uname -n), safari port id, and link number on both sides of the connection. The format of the information looks like this:</p> <pre> <nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno> <nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno> </pre> <p>This interface is intended for installing configurations for testing (such as for SunVTS). Only direct-connect, non-striped configurations for 1 to 3 nodes can be specified. FM node ids and RSM hardware addresses are assigned to the specified nodes contiguously and in order starting from 0.</p> <p>initial -f config_file [-c controller_id] Install the configuration for the local node stored in the file <i>config_file</i> into the driver as the initial configuration for the specified controller. This command fails under the following circumstances:</p> <ul style="list-style-type: none"> ■ If <i>controller_id</i> is specified and the configuration in the file is not for the specified controller. ■ If the file does not contain a valid configuration for the local node or if the checksum in the file shows it has been modified. ■ If a configuration has already been installed for the controller. If this happens, use <code>wrsmconf remove</code> to remove the existing configuration. <p>remove [-c controller_id] Disable communication through the installed configuration for all controllers or the specified controller and remove the configuration(s) from the driver.</p>

wrsmconf(1M)

`topology -c controller_id`

For each installed controller (or for the specified controller), print to stdout the set of nodes this controller is configured to reach, including the nodename, FM node id, and RSM hardware address for each node. The following is example output:

FM Node ID	Node Name	Controller Instance	Controller HW Addr
0	hpc00	0	101
0	hpc00	1	333
1	hpc01	0	102
1	hpc01	1	54
1	hpc01	2	34
2	hpc03	0	103
2	hpc03	1	103
2	hpc03	2	103

`dump -c controller-id -f config_file`

Fetch the installed configuration for the specified controller from the driver and store it into the file `config_file` along with a checksum to protect the data. This configuration can later be installed with the command `wrsmconf initial`.

EXIT STATUS This command returns 0 on successful completion, and a non-zero value if an error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwrsm

SEE ALSO `kstat(1M)`, `wrsmstat(1M)`, `attributes(5)`

NAME	wrsmstat – report WCI RSM driver statistics
SYNOPSIS	<pre> /opt/SUNWwrsm/bin/wrsmstat controller [-c controller_id] wrsmstat wrsm [-i wrsm_instance_num] [-v] wrsmstat route [-c controller_id] [-h node_hostname] wrsmstat set [-i wrsm_instance_num] -c cmmu -s start -e end </pre>
DESCRIPTION	<p>The wrsmstat command provides statistics on remote shared memory (RSM) controllers, routes to nodes, and WCI interfaces managed by the WCI RSM driver (wrsm). It also provides an interface for setting extended performance counter control registers that constrain the wrsm counters available through busstat(1M).</p>
OPTIONS	<p>The following options are supported:</p> <p>controller [-c controller_id] Displays information describing the state of the specified controller, or of all controllers if none is specified. The following is sample output:</p> <pre> \$ wrsmstat controller -c 5 Controller 5 ----- Controller state: up Local RSM Hardware address: 0x4 Exported segments: 0 # published: 0 # connections: 0 total bound memory: 0 Imported segments: 0 Send Queues: 0 Registered Handlers: 0 Assigned WCIs: 4 Available WCIs: 2 </pre> <p>wrsm [-i wrsm wrsm_instance_num] [-v] Displays information describing the state of the specified RSM WCI, or of all RSM WCIs if none is specified. The following is sample output:</p> <pre> \$ wrsmstat wrsm -i 7 WCI instance 7 ----- Portid: 5 Controller ID: 0 Config Version: 5 Link Error Shutdown Trigger: 40000 Link #0 is not present. Link #1 Link Enabled: yes Link State: up Remote RSM HW addr: 1 Remote wnode ID: 1 Remote link num: 1 Remote WCI port ID: 3 </pre>

wrsmstat(1M)

```
Error takedowns: 0
Bad Config takedowns: 0
Failed bringups: 0
Total link errors: 0
Maximum link errors: 0
Average link errors: 0
Auto shutdown enabled: yes
Link #2 is not present.
```

If you specify the `-v` option, the following additional information is displayed:

```
Cluster Error Count:      0
Uncorrectable SRAM ECC error:  no
Maximum SRAM ECC errors:  0
Average SRAM ECC errors:  0
```

`route [-c controller_id] [-h nodename]`

Displays the route to the specified node through the specified controller. If no node is specified, displays the routes to all nodes. If no controller is specified, displays the specified node's route through all controllers. If neither is specified, displays the routes to all nodes through all controllers. The following is sample output:

```
$ wrsmstat node -c 3 -h fred
Controller 3 - Route to fred
-----
Config Version: 1
FM node id: 0x345543
RSM hardware address: 0x9
Route Changes: 3

Number of WCIs: 2
Stripes: 4
WCI #0
  Port ID: 3
  Instance: 0
  Num of hops: 2
  Num of links: 2
    link# 1, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2
WCI #1
  Port ID: 13
  Instance: 1
  Num of hops: 2
  Num of links: 2
    link# 0, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2
```

`set [-i wrsm_instance_num] -c cmmu -s <start> -e <end>`

For the specified WCI (or for each RSM WCI if none specified), configure the specified range of CMMU entries so that transactions through them are counted by `wrsm busstat kstats`. Each call will cause transactions to be counted through the new ranges of cmmu entries in addition to the previously specified ranges. To count transactions through all CMMUs, specify a start value of 0 and end value of 0. To clear all ranges (and not count transactions through any cmmu entries), specify a start value of 0 and end value of -1.

wrsmstat(1M)

EXIT STATUS This command returns 0 on successful completion, and a non-zero value if an error occurred.

xntpd(1M)

NAME	xntpd – Network Time Protocol daemon
SYNOPSIS	<code>/usr/lib/inet/xntpd [-aAbdm] [-c <i>conffile</i>] [-e <i>authdelay</i>] [-f <i>driftfile</i>] [-k <i>keyfile</i>] [-l <i>logfile</i>] [-p <i>pidfile</i>] [-r <i>broadcastdelay</i>] [-s <i>statsdir</i>] [-t <i>trustedkey</i>] [-v <i>variable</i>] [-V <i>variable</i>]</code>
DESCRIPTION	<p>xntpd is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. xntpd is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by <i>RFC 1305</i>. It also retains compatibility with version 1 and 2 servers as defined by <i>RFC 1059</i> and <i>RFC 1119</i>, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source.</p> <p>Ordinarily, xntpd reads its configuration from a configuration file at startup time. The default configuration file name is <code>/etc/inet/ntp.conf</code>, although this may be overridden from the command line. It is also possible to specify a working, although limited, xntpd configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when xntpd is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the <code>ntpq(1M)</code> program, various internal xntpd variables can be displayed and configuration options altered while the daemon is running.</p> <p>The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.</p>
OPTIONS	<p>The following command line arguments are understood by xntpd. See <i>Configuration Commands</i> for a more complete functional description:</p> <ul style="list-style-type: none">-a Run in authentication mode.-A Disable authentication mode.-b Listen for broadcast NTP and sync to this if available.-c <i>conffile</i> Specify an alternate configuration file.-d Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.-e <i>authdelay</i> Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.-f <i>driftfile</i> Specify the location of the drift file.-k <i>keyfile</i> Specify the location of the file which contains the NTP authentication keys.

-l <i>logfile</i>	Specify a log file instead of logging to syslog.
-m	Listen for multicast messages and synchronize to them if available (requires multicast kernel).
-p <i>pidfile</i>	Specify the name of the file to record the daemon's process id.
-r <i>broadcast</i>	Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds).
-s <i>statsdir</i>	Specify the directory to be used for creating statistics files.
-t <i>trustedkey</i>	Add a key number to the trusted key list.
-v <i>variable</i>	Add a system variable.
-V <i>variable</i>	Add a system variable listed by default.

USAGE xntpd's configuration file format is similar to other Unix configuration files. Comments begin with a '#' character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted-decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

Configuration Commands

In the following descriptions, optional arguments are delimited by '[]', while alternatives are separated by '|'. The first three commands specify various time servers to be used and time services to be provided.

`peer host_address [key #] [version #] [prefer]`

Specifies that the local server is to operate in "symmetric active" mode with the remote server *host_address* named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The `peer` command, and the `server` and `broadcast` commands that follow, can take the following arguments:

<code>key</code>	Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included.
<code>version</code>	Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default.
<code>prefer</code>	Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts.

xntpd(1M)

`server host_address [key #] [version f1#] [prefer] [mode f1#] server`

Specifies that the local server is to operate in “client” mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.

`broadcast host_address [key #] [version #] [t1l #]`

Specifies that the local server is to operate in “broadcast” mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see `broadcastclient` or `multicastclient` commands elsewhere in this document. In broadcast mode the *host_address* is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network, 224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

`t1l` Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

`broadcastclient`

Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the “broadcastclient” mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

`multicastclient`

[*IP address . . .*] Used in the same way as the `broadcastclient` command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s). If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

`driftfile filename`

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write

permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

```
enable auth | bclient | pll | monitor | stats [...]
disable auth | bclient | pll | monitor | stats [...]
```

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.

Flag	Default	Description
<code>auth</code>	<code>disable</code>	Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier.
<code>bclient</code>	<code>disable</code>	Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. default for this flag is <code>disable</code> (off).
<code>pll</code>	<code>enable</code>	Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.
<code>monitor</code>	<code>disable</code>	Enables the monitoring facility (see elsewhere).
<code>stats</code>	<code>enable</code>	Enables statistics facility filegen (see <code>Monitoring Commands</code> below).

Authentication Commands

<code>keys <i>filename</i></code>	Specifies the name of a file which contains the encryption keys and key identifiers used by <code>xntpd</code> when operating in authenticated mode. The format of this file is described later in this document.
<code>trustedkey</code>	<code># [# . . .]</code> Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key 0 is fixed and globally known. If meaningful authentication is to be performed, the 0 key should not be trusted.

xntpd(1M)

	<code>controlkey #</code>	Specifies the key identifier to use with the <code>ntpq(1M)</code> program, which is useful to diagnose and repair problems that affect <code>xntpd</code> operation. The operation of the <code>ntpq</code> program and <code>xntpd</code> conform to those specified in <i>RFC 1305</i> . Requests from a remote <code>ntpq</code> program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no <code>controlkey</code> command is included in the configuration file, or if the keys don't match. These requests are ignored.
	<code>authdelay seconds</code>	Indicates the amount of time it takes to encrypt an NTP authentication field on the local computer. This value is used to correct transmit timestamps when the authentication is used on outgoing packets. The value usually lies somewhere in the range 0.0001 seconds to 0.003 seconds, though it is very dependent on the CPU speed of the host computer.
Access Control Commands	<code>restrict</code>	<p><code>address [mask numeric_mask] [flag] [...]</code></p> <p><code>xntpd</code> implements a general purpose address-and-mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted-quad format, the text string "default", with no mask option, may be used to indicate the default entry.</p> <p>In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server.</p> <p>One or more of the following flags may be specified:</p>

ignore	Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.
noquery	Ignore all NTP mode 7 packets (i.e., information queries and configuration requests) from the source. Time service is not affected.
nomodify	Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted.
notrap	Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs.
lowpriotrap	Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps.
noserve	Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted.
nopeer	Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners.

xntpd(1M)

<code>notrust</code>	Treat these hosts normally in other respects, but never use them as synchronization sources.
<code>limited</code>	<p>These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers to the IP notion of net (class A, class B, class C, etc.). Only the first <i>client_limit</i> hosts that have shown up at the server and that have been active during the last <i>client_limit_period</i> seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. "Private", "control", and "broadcast" packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of xntpd. Thus, monitoring is active as long as there is a restriction entry with the <code>limited</code> flag. The default value for <i>client_limit</i> is 3. The default value for <i>client_limit_period</i> is 3600 seconds. Currently both variables are not runtime configurable.</p>
<code>ntpport</code>	<p>This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard NTP UDP port (123). Both <code>ntpport</code> and <code>non-ntpport</code> may be specified. The <code>ntpport</code> is considered more specific and is sorted later in the list.</p> <p>Default restriction list entries, with the flags, <code>ignore</code>, <code>ntpport</code>, for each of the local host's interface addresses are inserted into the table at startup to prevent the server</p>

from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with xntpd as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

`clientlimit limit`

Sets *client_limit* to *limit*; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server.

`clientperiod period`

Sets *client_limit_period*; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction.

Monitoring Commands

`statsdir /directory path/`

Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) `filegen` filename prefix to be modified for file generation sets used for handling statistics logs (see `filegen` statement below).

`statistics name ...`

Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its *name*, a sample line of data, and an explanation of each field:

`loopstats` enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named "loopstats":

xntpd(1M)

	48773 10847.650 0.0001307 17.3478 2
Field No.	Description
1	The date (Modified Julian day)
2	The time (seconds and fraction past UTC midnight)
3	Time offset in seconds
4	Frequency offset in parts-per-million
5	Time constant of the clock-discipline algorithm at each update of the clock
peerstats	enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats":
	48773 10847.650 127.127.4.1 9714 -0.001605 \ 0.00000 0.00142
Field No.	Description
1	The date (Modified Julian Day)
2	The time (seconds and fraction past UTC midnight)
3	The peer address in dotted-quad notation
4	peer status. The status field is encoded in hex in the format described in Appendix A of the NTP specification, <i>RFC 1305</i> .
5	Offset in seconds
6	Delay in seconds
7	Dispersion in seconds
clockstats	enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats":
	49213 525.624 127.127.4.1 93 226 \ 00:08:29.606 D
Field No.	Description
1	The date (Modified Julian Day)
2	The time (seconds and fraction past UTC midnight)
3	The clock address in dotted-quad notation
4	The last timecode received from the clock in decoded ASCII format, where meaningful

In some clock drivers a good deal of additional information can be gathered and displayed as well.

Statistic files are managed using file generation sets (see `filegen` below). The information obtained by enabling statistics recording allows analysis of temporal properties of a `xntpd` server. It is usually only useful to primary servers or maybe main campus servers.

```
filegen name [ file filename ] [ type typename ] [ flag flagval ] [ link | nolink ]
[ enable | disable ]
```

Configures setting of generation file set *name*. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The `type` given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of `xntpd`. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

prefix This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with “loopstats” and “peerstats” filegens can be configured using the `statsdir` statement explained above.

filename This string is directly concatenated to the *prefix* mentioned above (no intervening ‘/’ (slash)). This can be modified using the `file` argument to the `filegen` statement. No ‘.’ elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by *prefix*.

suffix This part reflects individual elements of a file set. It is generated according to the `type` of a file set as explained below. A file generation set is characterized by its type. The following types are supported:

`none` The file set is actually a single plain file.

`pid` One element of file set is used per incarnation of a `xntpd` server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different `xntpd` server incarnations. The set member filename is built by appending a ‘.’ (dot) to concatenated *prefix* and *filename* strings, and appending the decimal representation of the process id of the `xntpd` server process.

`day` One file generation set element is created per day. The term *day* is based on UTC. A day is defined as the period between 00:00 and 24:00 UTC. The

xntpd(1M)

file set member suffix consists of a '.' (dot) and a day specification in the form, *YYYYMMDD*. *YYYY* is a 4 digit year number (e.g., 1992). *MM* is a two digit month number. *DD* is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, *PrefixFilename.19921210*.

- week** Any file set member contains data related to a certain week of a year. The term *week* is defined by computing "day of year" modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter 'W', and a two digit week number. For example, information from January, 5th 1992 would end up in a file with suffix ".1992W1".
- month** One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month.
- year** One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number.
- age** This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter 'a', and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period.

Information is only written to a file generation set when this set is enabled. Output is prevented by specifying, *disabled*.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying *link* and disabled using *noLink*. If *link* is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter, 'C', and the pid of the xntpd server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

Miscellaneous Commands

precision #

Specifies the nominal precision of the local clock. The value of, # is an integer approximately equal to the base 2 logarithm of the local timekeeping precision in seconds. Normally, the daemon determines the precision automatically at startup. So this command is necessary only in special cases when the precision cannot be determined automatically.

broadcastdelay seconds

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be

used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for *seconds*. When this command is not used, the default is 0.004 seconds.

`trap host_address [port port_number][interface interface_address]`

Configures a trap receiver at the given *host_address* and *port_number* for sending messages with the specified local *interface_address*. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with the source address of the local interface the message is sent through. On a multi-homed host, the interface used may change with routing changes.

C information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that no messages are lost when the server is started.

`setvar variable [default]`

This command adds an additional system variable. Variables like this can be used to distribute additional information such as the access policy. If the variable of the form, *variable_name=value* is followed by the *default* keyword, the variable will be listed as one of the default system variables (see the `ntpqc(1M)` command). Additional variables serve informational purposes only. They can be listed; but they are not related to the protocol. The known protocol variables always override any variables defined via the `setvar` mechanism.

Three special variables contain the names of all variable of the same group. *sys_var_list* holds the names of all system variables. *peer_var_list* holds the names of all peer variables. And *clock_var_list* hold the names of the reference clock variables.

`monitor [yes | no]`

`authenticate [yes | no]`

These commands have been superseded by the `enable` and `disable` commands. They are listed here for historical purposes.

`logconfig configkeyword`

Controls the amount of output written to syslog or the logfile. By default all output is turned on. *configkeyword* is formed by concatenating the message class with the event class. It is permissible to use the prefix, `all`, instead of a message class. A message class may also be followed by the keyword, `all`, meaning to enable/disable all of the respective message class. All *configkeywords* can be prefixed with the symbols, '=', '+' and '-'. Here, '=' sets the syslogmask, '+' adds messages, and '-' removes messages. Syslog messages can be controlled in four classes: *sys*, *peer*, *clock*, *sync*. Within these classes four types of messages can be controlled. Each is described below, along with its `configkeyword`:

Configkeyword	Message type
<code>info</code>	Informational messages control configuration information.
<code>events</code>	Event messages control logging of events (reachability, synchronization, alarm conditions).

xntpd(1M)

`statistics` Statistical messages control statistical output.
`status` Status messages describe mainly the synchronization status.

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of `xntpd` and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.

Authentication Key File Format

The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in `xntpd` using the DES or MD5 algorithms to compute a digital signature, or message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). `xntpd` reads its keys from a file specified using the `-k` command line option or the `keys` statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, *keyno type key*. Here, *keyno* is a positive integer, *type* is a single character which defines the format the key is given in, and *key* is the key itself.

The *key* may be given in one of several different formats, controlled by the *type* character. The different key types, and corresponding formats, are described below:

Key: S

Format : A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key, in standard format, would be given as: 0101010101010101.

Key: N

Format : A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: 8080808080808080.

Key: A

Format: A 1-to-8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string. Zeroes are added on the right when necessary to form a full width 56 bit key.

Key: S

Format: A 1-to-8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support

xntpd has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, xntpd treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form *127.127.t.u* where *t* is an integer denoting the clock type and *u* indicates the type-specific unit number. Reference clocks are configured using a `server` statement in the configuration file where the `host_address` is the clock address. The `key`, `version` and `ttl` options are not used for reference clock support. Some reference clocks require a `mode` option to further specify their operation. The `prefer` option can be useful to persuade the server to cherish a reference clock with somewhat more enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in `restrict` statements, although such use would normally be considered strange.

Reference clock support provides the `fudge` command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is,

```
fudge 127.127.t.u [ time1 secs ] [ time2 secs ] [ stratum int ] [ refid int ]
      [ flag1 0|1 ] [ flag2 0|1 ] [ flag3 0|1 ] [ flag4 0|1 ]
```

xntpd(1M)

with options described as follows:

<i>time1</i>	
<i>time2</i>	Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, <i>time1</i> is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.
<i>stratum</i>	Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.
<i>refid</i>	Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.
<i>flag1</i>	
<i>flag2</i>	
<i>flag3</i>	
<i>flag4</i>	Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, <i>flag3</i> is used to attach the ppsclock streams module to the configured driver, while <i>flag4</i> is used to enable recording verbose monitoring data to the clockstats file configured with the <code>filegen</code> command. Further information on the ppsclock streams module is in the README file in the <code>./kernel</code> directory in the current xntp3 program distribution. Further information on this feature is available in the <code>./scripts/stats</code> directory in the same distribution.

Ordinarily, the stratum of a reference clock is zero, by default. Since the xntpd daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The `stratum` option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The `refid` option is used for this purpose. Except where noted, these options apply to all clock drivers.

xntpd on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo-clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the README file in the `./doc` directory of the xntp3 program distribution. The clock drivers, and the addresses used to configure them, are described in the file, `README.refclocks`, in the `doc` directory of the current program distribution.

Variables Most variables used by the NTP protocol can be examined with `ntpq` (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These

variables are either created with the `setvar` directive or the leap warning variables. The leap warning bits that can be set in the `leapwarning` variable (up to one month ahead). Both, the `leapwarning` and in the `leapindication` variable, have a slightly different encoding than the usual leap bits interpretation:

00 The daemon passes the leap bits of its synchronization source (usual mode of operation).
 01/10 A leap second is added/deleted (operator forced leap second).
 11 Leap information from the synchronization source is ignored (thus LEAP_NOWARNING is passed on).

FILES /etc/inet/ntp.conf Default name of the configuration file
 /etc/inet/ntp.drift Conventional name of the drift file
 /etc/inet/ntp.keys Conventional name of the key file
 /etc/inet/ntp.server Sample server configuration file

xntpdc(1M)

NAME	xntpdc – special NTP query program										
SYNOPSIS	xntpdc [-ilnps] [-c <i>command</i>] [<i>host</i>] [...]										
DESCRIPTION	<p>xntpdc queries the xntpd daemon about its current state and requests changes in that state. You can run xntpdc in interactive mode or in controlled using command line arguments.</p> <p>Extensive state and statistics information is available through the xntpdc interface. In addition, nearly all the configuration options which can be specified at start up using xntpd's configuration file may also be specified at run time using xntpdc.</p> <p>If one or more request options is included on the command line when xntpdc is executed, each of the requests is sent to the NTP servers running on each of the hosts given as command line arguments, or on the local host by default. If no request options are given, xntpdc attempts to read commands from the standard input and execute these on the NTP server running on the first host specified on the command line, again defaulting to the local host when no other host is specified. xntpdc prompts for commands if the standard input is a terminal device.</p> <p>xntpdc uses NTP mode 7 packets to communicate with the NTP server, and can be used to query any compatible server on the network which permits it. As NTP is a UDP protocol, this communication is somewhat unreliable, especially over large distances. xntpdc does not attempt to re-transmit requests, and times requests out if the remote host is not heard from within a suitable timeout time.</p> <p>The operation of xntpdc is specific to the particular implementation of the xntpd daemon. You can expect xntpdc to work only with this and maybe some previous versions of the daemon. Requests from a remote xntpdc program that affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier.</p>										
OPTIONS	<p>xntpdc reads interactive format commands from the standard input. If you specify the -c, -l, -p or -s option, the specified queries are sent to the hosts immediately.</p> <p>The following command line options are supported:</p> <table><tr><td>-c <i>command</i> . . .</td><td>Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.</td></tr><tr><td></td><td>Multiple -c options may be specified.</td></tr><tr><td>-i</td><td>Force xntpdc to operate in interactive mode.</td></tr><tr><td></td><td>Prompts are written to the standard output. Commands are read from the standard input.</td></tr><tr><td>-l</td><td>Obtain a list of peers which are known to the servers.</td></tr></table>	-c <i>command</i> . . .	Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.		Multiple -c options may be specified.	-i	Force xntpdc to operate in interactive mode.		Prompts are written to the standard output. Commands are read from the standard input.	-l	Obtain a list of peers which are known to the servers.
-c <i>command</i> . . .	Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.										
	Multiple -c options may be specified.										
-i	Force xntpdc to operate in interactive mode.										
	Prompts are written to the standard output. Commands are read from the standard input.										
-l	Obtain a list of peers which are known to the servers.										

	This option is equivalent to <code>-c listpeers</code> . See <code>listpeers</code> in Control Message Commands.
<code>-n</code>	Output all host addresses in dotted-quad numeric format rather than converting to the canonical host names.
<code>-p</code>	Print a list of the peers known to the server as well as a summary of their state.
	This option is equivalent to <code>-c peers</code> . See <code>peers</code> in Control Message Commands.
<code>-s</code>	Print a list of the peers known to the server as well as a summary of their state, but in a slightly different format than the <code>-p</code> option. This option is equivalent to <code>-c dmpeers</code> . See <code>dmpeers</code> in Control Message Commands.

OPERANDS The following operands are supported:

Interactive Commands

The interactive commands consist of a keyword (*command_keyword*) followed by zero to four arguments. You need to enter only enough characters of the *command_keyword* to uniquely identify it. The output of an interactive command is sent to the standard output by default. You can send the output of an interactive command to a file by appending a `<`, followed by a file name, to the command line.

A number of interactive format commands are executed entirely within the `xntpd` program itself and do not result in NTP mode.

The following interactive commands are supported:

<code>? [<i>command_keyword</i>]</code>	Without an argument, print a list of <code>ntpq</code> command keywords. If <i>command_keyword</i> is specified, print function and usage information about the <i>command_keyword</i> .
<code>delay <i>milliseconds</i></code>	Specify a time interval to add to timestamps included in requests which require authentication.
	This enables (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Because the server no longer requires timestamps in authenticated requests, this command may be obsolete.
<code>help [<i>command_keyword</i>]</code>	Without an argument, print a list of <code>ntpq</code> command keywords. If <i>command_keyword</i> is

xntpdc(1M)

	specified, print function and usage information about the <i>command_keyword</i> .
host <i>hostname</i>	Set the host (<i>hostname</i>) to which future queries are sent. Specify <i>hostname</i> as a host name or a numeric address.
hostnames [yes no]	Print hostnames or numeric addresses in information displays. Specify <i>yes</i> to print host names. Specify <i>no</i> to print numeric addresses. The default is <i>yes</i> , unless the <i>-n</i> command line option is specified.
keyid <i>keyid</i>	Enable specification of a key number (<i>keyid</i>) to authenticate configuration requests. <i>keyid</i> must correspond to a key number the server has been configured to use for this purpose.
passwd	Prompt user to enter a password to authenticate configuration requests. The password is not displayed, and must correspond to the key configured for use by the NTP server for this purpose. If the password does not correspond to the key configured for use by the NTP server, requests are not successful.
quit	Exit xntpdc.
timeout <i>milliseconds</i>	Specify a timeout period for responses to server queries. The default is approximately 8000 milliseconds. As xntpdc retries each query once after a timeout, the total waiting time for a timeout is twice the timeout value set.
Control Message Commands	Query commands result in NTP mode 7 packets containing requests for information being sent to the server. These control message commands are read-only commands in that they make no modification of the server configuration state. The following control message commands are supported: clkbug Obtain debugging information for a reference clock driver. This information is provided only by some clock drivers.

`clockinfo clock_peer_address [...]`

Obtain and print information concerning a peer clock.

The values obtained provide information on the setting of fudge factors and other clock performance information.

`dmpeers`

Obtain a list of peers for which the sserver is maintaining state, along with a summary of that state.

The peer summary list is identical to the output of the `peers` command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A `.` indicates that this peer was cast off in the falseticker detection, while a `+` indicates that the peer made it through. A `*` denotes the peer with which the server is currently synchronizing.

`iostats`

Print statistics counters maintained in the input-output module.

`kerninfo`

Obtain and print kernel phase-lock loop operating parameters.

This information is available only if the kernel has been specially modified for a precision timekeeping function.

`listpeers`

Obtain and print a brief list of the peers for which the server is maintaining state.

These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchronization candidates.

`loopinfo [oneline | multiline]`

Print the values of selected loop filter variables.

The loop filter is the part of NTP which deals with adjusting the local system clock.

The `oneline` and `multiline` options specify the format in which this information is printed. `multiline` is the default.

The `offset` is the last offset given to the loop filter by the packet processing code. The `frequency` is the frequency error of the local clock in parts-per-million (ppm). The `time_const` controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The `watchdog` timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter.

`memstats`

Print statistics counters related to memory allocation code.

xntpd(1M)

monlist [version]

Obtain and print traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified.

peers

Obtain a list of peers for which the server is maintaining state, along with a summary of that state.

The following summary information is included:

- Address of the remote peer.
- Local interface address. If a local address has yet to be determined it is 0 . 0 . 0 . 0 .
- Stratum of the remote peer. A stratum of 16 indicates the remote peer is unsynchronized.
- Polling interval, in seconds.
- Reachability register, in octal.
- Current estimated delay, offset and dispersion of the peer, in seconds.
- Mode in which the peer entry is operating.

This is represented by the character in the left margin. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchronizing to.

- Host.

This field may contain a host name, an IP address, a reference clock implementation name with its parameter or REFCLK (implementation number, parameter). On hostnames no only IP-addresses is displayed.

pstats *peer_address* [...]

Show the per-peer statistic counters associated with the specified peers.

reslist

Obtain and print the server's restriction list.

Generally, this list is printed in sorted order.

showpeer *peer_address* [...]

Show a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification.

sysinfo

Print a variety of system state variables that are related to the local server.

The output from `sysinfo` is described in NTP Version 3 specification, RFC-1305. All except the last four lines are described in the NTP Version 3 specification, RFC-1305.

The `system flags` show various system flags, some of which can be set and cleared by the `enable` and `disable` configuration commands, respectively. These are the `auth`, `bclient`, `monitor`, `pll`, `pps` and `stats` flags. See the `xntpd` documentation for the meaning of these flags. There are two additional flags which are read only, the `kernel_pll` and `kernel_pps`. These flags indicate the synchronization status when the precision time kernel modifications are in use. The `kernel_pll` indicates that the local clock is being disciplined by the kernel, while the `kernel_pps` indicates the kernel discipline is provided by the PPS signal. The `stability` is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value initially decreases from as high as 500 ppm to a nominal value in the range .01 to 0.1 ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the kernel variable `tick` may be incorrect. The `broadcastdelay` shows the default broadcast delay, as set by the `broadcastdelay` configuration command. The `authdelay` shows the default authentication delay, as set by the `authdelay` configuration command.

`sysstats`

Print statistics counters maintained in the protocol module.

`timerstats`

Print statistics counters maintained in the timer/event queue support code.

Runtime Configuration Requests

The server authenticates all requests that cause state changes in the server. The server uses a configured NTP key to accomplish this. This facility can also be disabled by the server by not configuring a key).

You must make the key number and the corresponding key known to `xntpd`. Use the `keyid` or `passwd` commands to do so.

The `passwd` command prompts users for a password to use as the encryption key. It also prompts automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication provides verification that the requester has permission to make such changes. It also gives an extra degree of protection against transmission errors.

Authenticated requests always include a time stamp in the packet data. The time stamp is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If the time stamps differ by more than a small amount the request is rejected.

Time stamps are rejected for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more

xntpd(1M)

difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts.

While the reconfiguration facility works well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it works very poorly for more distant hosts. If reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the run time reconfiguration facility should provide an adequate level of security.

The following commands make authenticated requests.

`addpeer peer_address [keyid] [version] [prefer]`

Add a configured peer association at the given address and operating in symmetric active mode. An existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate.

If the optional *keyid* is a non-zero integer, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the *keyid* is 0 or omitted, no authentication is done.

Specify *version* as 1, 2 or 3. The default is 3.

The *prefer* keyword indicates a preferred peer. This keyword is used primarily for clock synchronisation if possible. The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronisation so is the PPS signal.

`addserver peer_address [keyid] [version] [prefer]`

Identical to the `addpeer` command, except that the operating mode is client.

`addtrap [address [port] [interface]`

Set a trap for asynchronous messages.

`authinfo`

Return information concerning the authentication module, including known keys and counts of encryptions and decryptions which have been done.

`broadcast peer_address [keyid] [version] [prefer]`

Identical to the `addpeer` command, except that the operating mode is broadcast. In this case a valid key identifier and key are required. The *peer_address* parameter can be the broadcast address of the local network or a multicast group address assigned to NTP. If a multicast address, a multicast-capable kernel is required.

`clrtrap [address [port] [interface]`

Clear a trap for asynchronous messages.

`delrestrict address mask [ntpport]`

Delete the matching entry from the restrict list.

`fudge peer_address [time1] [time2] [stratum] [refid]`

Provide a way to set certain data for a reference clock.

`readkeys`

Cause the current set of authentication keys to be purged and a new set to be obtained by re-reading the `keys` file. The `keys` file must have been specified in the `xntpd` configuration file. This enables encryption keys to be changed without restarting the server.

`restrict address mask flag [flag]`

This command operates in the same way as the `restrict` configuration file commands of `xntpd`.

`reset`

Clear the statistics counters in various modules of the server.

`traps`

Display the traps set in the server.

`trustkey keyid [...]`

`untrustkey keyid [...]`

These commands operate in the same way as the `trustedkey` and `untrustkey` configuration file commands of `xntpd`.

`unconfig peer_address [...]`

Cause the configured bit to be removed from the specified peers. In many cases this causes the peer association to be deleted. When appropriate, however, the association may persist in an unconfigured mode if the remote peer is willing to continue on in this fashion.

`unrestrict address mask flag [flag]`

Unrestrict the matching entry from the `restrict` list.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

ypbind(1M)

NAME	ypbind – NIS binder process		
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypbind</code> [-broadcast -ypset -ypsetme]		
DESCRIPTION	<p>NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in <code>ypclnt(3NSL)</code>. Administrative tools are described in <code>ypinit(1M)</code>, <code>ypwhich(1)</code>, and <code>ypset(1M)</code>. Tools to see the contents of NIS maps are described in <code>ypcat(1)</code>, and <code>ypmatch(1)</code>.</p> <p><code>ypbind</code> is a daemon process that is activated at system startup time from the startup script <code>/etc/init.d/rpc</code>. By default, it is invoked as <code>ypbind -broadcast</code>. <code>ypbind</code> runs on all client machines that are set up to use NIS. See <code>sysidtool(1M)</code>. The function of <code>ypbind</code> is to remember information that lets all NIS client processes on a node communicate with some NIS server process. <code>ypbind</code> must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. If the NIS server is a NIS+ server in NIS (YP) compatibility mode, see the NOTES section of the <code>ypfiles(4)man</code> page for more information.</p> <p>The information <code>ypbind</code> remembers is called a <i>binding</i> — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the <code>-broadcast</code> option, the <code>ypbind</code> process broadcasts on the net trying to find an NIS server, either a <code>ypserv</code> process serving the domain or an <code>rpc.nisd</code> process in "YP-compatibility mode" serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the <code>-broadcast</code> option, <code>ypbind</code> process steps through the list of NIS servers that was created by <code>ypinit -c</code> for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in either the <code>/etc/hosts</code> or <code>/etc/inet/ipnodes</code> files along with their IP addresses. Once a domain is bound by <code>ypbind</code>, that same binding is given to every client process on the node. The <code>ypbind</code> process on the local node or a remote node may be queried for the binding of a particular domain by using the <code>ypwhich(1)</code> command.</p> <p>If <code>ypbind</code> is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, <code>ypbind</code> will try to bind to another NIS server using the process described above. <code>ypbind</code> also accepts requests to set its binding for a particular domain. The request is usually generated by the <code>ypset(1M)</code> command. In order for <code>ypset</code> to work, <code>ypbind</code> must have been invoked with flags <code>-ypset</code> or <code>-ypsetme</code>.</p>		
OPTIONS	<table><tr><td><code>-broadcast</code></td><td>Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.</td></tr></table>	<code>-broadcast</code>	Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.
<code>-broadcast</code>	Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.		

ypbind(1M)

This option is analogous to `ypbind` with no options in earlier Sun releases and is recommended for ease of use.

`-ypset`

Allow users from any remote machine to change the binding by means of the `ypset` command. By default, no one can change the binding. This option is insecure.

`-ypsetme`

Only allow `root` on the local machine to change the binding to a desired server by means of the `ypset` command. `ypbind` can verify the caller is indeed a `root` user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

FILES `/var/yp/binding/ypdomain/ypservers`
`/etc/inet/hosts`
`/etc/inet/ipnodes`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `ypcat(1)`, `ypmatch(1)`, `ypwhich(1)`, `ifconfig(1M)`, `rpc.nisd(1M)`, `ypinit(1M)`, `ypset(1M)`, `ypclnt(3NSL)`, `hosts(4)`, `ipnodes(4)`, `ypfiles(4)`, `attributes(5)`

NOTES `ypbind` supports multiple domains. The `ypbind` process can maintain bindings to several domains and their servers, the default domain is the one specified by the `domainname(1M)` command at startup time.

The `-broadcast` option works only on the UDP transport. It is insecure since it trusts "any" machine on the net that responds to the broadcast request and poses itself as an NIS server.

ypinit(1M)

NAME	ypinit – set up NIS client						
SYNOPSIS	<code>/usr/sbin/ypinit [-c] [-m] [-s <i>master_server</i>]</code>						
DESCRIPTION	<p>ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the start up script /etc/init.d/rpc).</p> <p>Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.</p> <p>ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers must be listed in either the /etc/hosts or the /etc/inet/ipnodes file along with its IP address. ypinit stores the list in file /var/yp/binding/domain/ypservers. This file is used by ypbind when run without the -broadcast option.</p>						
OPTIONS	<table><tr><td>-c</td><td>Set up a ypclient system.</td></tr><tr><td>-m</td><td>Build a master ypserver data base.</td></tr><tr><td>-s <i>master_server</i></td><td>Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.</td></tr></table>	-c	Set up a ypclient system.	-m	Build a master ypserver data base.	-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.
-c	Set up a ypclient system.						
-m	Build a master ypserver data base.						
-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.						
FILES	<p>/etc/hosts</p> <p>/etc/inet/ipnodes</p> <p>/var/yp/binding/domain/ypservers</p>						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnisu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWnisu						
SEE ALSO	ypbind(1M), sysinfo(2), hosts(4), ipnodes(4), attributes(5)						
BUGS	ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the SI_SRPC_DOMAIN command to sysinfo(2). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.						

NAME	ypmake – rebuild NIS database								
SYNOPSIS	cd /var/yp ; make [<i>map</i>]								
DESCRIPTION	<p>The file called <code>Makefile</code> in <code>/var/yp</code> is used by <code>make(1)</code> to build the Network Information Service (NIS) database. With no arguments, <code>make</code> creates <code>dbm</code> databases for any NIS maps that are out-of-date, and then executes <code>yppush(1M)</code> to notify slave databases that there has been a change.</p> <p>If you supply a <i>map</i> on the command line, <code>make</code> will update that map only. Typing <code>make passwd</code> will create and <code>yppush</code> the password database (assuming it is out of date). Likewise, <code>make ipnodes</code> and <code>make networks</code> will create and <code>yppush</code> the <code>ipnodes</code> and <code>network</code> files, <code>\$(INETDIR)/ipnodes</code> and <code>\$(DIR)/networks</code>.</p> <p>There are four special variables used by <code>make</code>: <code>DIR</code>, which gives the directory of the source files; <code>NOPUSH</code>, which when non-null inhibits doing a <code>yppush</code> of the new database files; <code>INETDIR</code>, which gives the directory of the <code>ipnodes</code> source file; and <code>DOM</code>, which is used to construct a domain other than the master's default domain. The default for <code>DIR</code> is <code>/etc</code>, and the default for <code>INETDIR</code> is <code>/etc/inet</code>. The default for <code>NOPUSH</code> is the null string.</p> <p>Refer to <code>ypfiles(4)</code> and <code>ypserv(1M)</code> for an overview of the NIS service.</p>								
FILES	<table> <tr> <td><code>/var/yp</code></td> <td>Directory containing NIS configuration files.</td> </tr> <tr> <td><code>/etc/inet/hosts</code></td> <td>System hosts file.</td> </tr> <tr> <td><code>/etc/inet</code></td> <td>Default directory for <code>ipnodes</code> source file.</td> </tr> <tr> <td><code>/etc</code></td> <td>Default directory for source files other than <code>ipnodes</code>.</td> </tr> </table>	<code>/var/yp</code>	Directory containing NIS configuration files.	<code>/etc/inet/hosts</code>	System hosts file.	<code>/etc/inet</code>	Default directory for <code>ipnodes</code> source file.	<code>/etc</code>	Default directory for source files other than <code>ipnodes</code> .
<code>/var/yp</code>	Directory containing NIS configuration files.								
<code>/etc/inet/hosts</code>	System hosts file.								
<code>/etc/inet</code>	Default directory for <code>ipnodes</code> source file.								
<code>/etc</code>	Default directory for source files other than <code>ipnodes</code> .								
SEE ALSO	<code>make(1)</code> , <code>nis+(1)</code> , <code>makedbm(1M)</code> , <code>rpc.nisd(1M)</code> , <code>ypbind(1M)</code> , <code>yppush(1M)</code> , <code>ypserv(1M)</code> , <code>ypclnt(3NSL)</code> , <code>ypfiles(4)</code> , <code>ipnodes(4)</code>								
NOTES	<p>The NIS <code>makefile</code> is only used when running the <code>ypserv(1M)</code> server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see <code>rpc.nisd(1M)</code>; this <code>makefile</code> is not relevant. See <code>ypfiles(4)</code> for more details.</p> <p>The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.</p>								

yppoll(1M)

- NAME** yppoll – return current version of a NIS map at a NIS server host
- SYNOPSIS** /usr/sbin/yppoll [-d *ypdomain*] [-h *host*] *mapname*
- DESCRIPTION** The yppoll command asks a ypserv() process what the order number is, and which host is the master NIS server for the named map.
- OPTIONS**
- d *ypdomain* Use *ypdomain* instead of the default domain.
 - h *host* Ask the ypserv process at *host* about the map parameters. If *host* is not specified, the NIS server for the local host is used. That is, the default host is the one returned by ypwhich(1).
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

NAME	yppush – force propagation of changed NIS map				
SYNOPSIS	<code>/usr/lib/netsvc/yp/yppush [-v] [-h <i>host</i>] [-d <i>domain</i>] [-p #<i>parallel-xfrs</i>] <i>mapname</i></code>				
DESCRIPTION	<p>yppush copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the <code>Makefile</code> in <code>/var/yp</code> after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS <code>ypservers</code> map within the <i>domain</i>. Keys within the <code>ypservers</code> map are the ASCII names of the machines on which the NIS servers run.</p> <p>A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program which actually moves the map) to call back the yppush. When the attempt has completed (successfully or not), and the transfer agent has sent yppush a status message, the results may be printed to stdout. Messages are also printed when a transfer is not possible; for instance when the request message is undeliverable, or when the timeout period on responses has expired.</p> <p>Refer to <code>ypfiles(4)</code> and <code>ypserv(1M)</code> for an overview of the NIS service.</p>				
OPTIONS	<p><code>-d <i>domain</i></code> Specify a <i>domain</i>.</p> <p><code>-h <i>host</i></code> Propagate only to the named <i>host</i>.</p> <p><code>-p #<i>parallel-xfrs</i></code> Allow the specified number of map transfers to occur in parallel.</p> <p><code>-v</code> Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.</p>				
FILES	<p><code>/var/yp</code> Directory where NIS configuration files reside.</p> <p><code>/var/yp/<i>domain</i>/ypservers. {<i>dir</i>, <i>pag</i> }</code> Map containing list of NIS servers to bind to when running in server mode.</p>

NOTES	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The				

yppush(1M)

name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

BUGS In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.

NAME	ypserv, ypxfrd – NIS server and binder processes		
SYNOPSIS	<pre> /usr/lib/netsvc/yp/ypserv [-dv] /usr/lib/netsvc/yp/ypxfrd </pre>		
DESCRIPTION	<p>The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See dbm_clearerr(3C). These files are described in ypfiles(4). The processes are /usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind, the NIS binder. The programmatic interface to the NIS service is described in ypclnt(3NSL). Administrative tools are described in yppoll(1M), yppush(1M), ypset(1M), ypxfr(1M), and ypwhich(1). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1). Database generation and maintenance tools are described in ypinit(1M), ypmake(1M), and makedbm(1M).</p> <p>The ypserv utility is a daemon process typically activated at system startup time from /etc/init.d/rpc. Alternatively, NIS services can also be started using ypstart(1M) from the command-line as the root user. ypserv runs only on NIS server machines with a complete NIS database. All NIS services can be halted using the ypstop(1M) command.</p> <p>The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, ypxfrd should be run on the master server. See /usr/lib/netsvc/yp/ypstart. ypxfr attempts to use ypxfrd first, if that fails, it prints a warning and then uses the older transfer method.</p> <p>The ypserv daemon's primary function is to look up information in its local database of NIS maps.</p> <p>The operations performed by ypserv are defined for the implementor by the <i>YP Protocol Specification</i>, and for the programmer by the header file <code>rpcsvc/yp_prot.h</code>.</p> <p>Communication to and from ypserv is by means of RPC calls. Lookup functions are described in ypclnt(3NSL), and are supplied as C-callable functions in the libnsl(3LIB) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: yp_match(3NSL), yp_first(3NSL), yp_next(3NSL), and yp_all(3NSL). The yp_match operation takes a key, and returns the associated value. The yp_first operation returns the first key-value pair from the map, and yp_next can be used to enumerate the remainder. yp_all ships the entire map to the requester as the response to a single RPC request.</p> <p>There are a number of special keys in the DBM files that can alter the way in which ypserv operates. The keys of interest are:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">YP_INTERDOMAIN</td> <td>The presence of this key causes ypserv to forward host lookups that cannot be satisfied by the DBM files to a DNS server.</td> </tr> </table>	YP_INTERDOMAIN	The presence of this key causes ypserv to forward host lookups that cannot be satisfied by the DBM files to a DNS server.
YP_INTERDOMAIN	The presence of this key causes ypserv to forward host lookups that cannot be satisfied by the DBM files to a DNS server.		

ypserv(1M)

YP_SECURE This key causes `ypserv` to only answer questions coming from clients on reserved ports.

YP_MULTI_hostname This is a special key in the form, `YP_MULTI_hostname addr1,...,addrN`. A client looking for `hostname` has the “closest” address returned.

Two other functions supply information about the map, rather than map entries: `yp_order(3NSL)`, and `yp_master(3NSL)`. In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with `makedbm(1M)`, however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. They include `do_you_serve_this_domain?`, `transfer_map`, and `reinitialize_internal_state`.

ypserv `-d` The NIS service should go to the DNS (Domain Name Service) for more host information. This requires the existence of a correct `/etc/resolv.conf` file pointing at a machine running `in.named(1M)`. This option turns on DNS forwarding regardless of whether or not the `YP_INTERDOMAIN` flag is set in the hosts maps. See `makedbm(1M)`. In the absence of an `/etc/resolv.conf` file, `ypserv` complains, but ignores the `-d` option.

`-v` Operate in the verbose mode, printing diagnostic messages to `stderr`.

FILES `/var/yp/securenets` Defines the hosts and networks which are granted access to information in the served domain; it is read at startup time by both `ypserv` and `ypxfrd`.

`/etc/init.d/rpc` Startup file that starts up basic RPC services, and NIS by calling `ypstart(1M)` If the `/var/yp/ypserv.log` file exists when `ypserv` starts up, log information will be written to it when error conditions arise. The file `/var/yp/binding/domainname/ypservers` is used to list the NIS server hosts that `ypbind` will bind to.

Network Interface Guide

System Administration Guide, Volume 1

NOTES ypserv supports multiple domains. The ypserv process determines the domains it serves by looking for directories of the same name in the directory `/var/yp`. It replies to all broadcasts requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

ypset(1M)

NAME	ypset – point ypbind at a particular server				
SYNOPSIS	<code>/usr/sbin/ypset [-d <i>ypdomain</i>] [-h <i>host</i>] <i>server</i></code>				
DESCRIPTION	<p>In order to run <code>ypset</code>, <code>ypbind</code> must be initiated with the <code>-ypset</code> or <code>-ypsetme</code> options. See <code>ypbind(1M)</code>. <code>ypset</code> tells <code>ypbind</code> to get NIS services for the specified <i>ypdomain</i> from the <code>ypserv</code> process running on <i>server</i>. If <i>server</i> is down, or is not running <code>ypserv</code>, this may not be discovered until an NIS client process tries to get a binding for the domain. At this point, the binding set by <code>ypset</code> will be tested by <code>ypbind</code>. If the binding is invalid, <code>ypbind</code> will attempt to rebind for the same domain.</p> <p><code>ypset</code> is useful for binding a client node which is not on a broadcast net, or is on a broadcast net which is not running a NIS server host. It also is useful for debugging NIS client applications, for instance where a NIS map only exists at a single NIS server host.</p> <p>In cases where several hosts on the local net are supplying NIS services, it is possible for <code>ypbind</code> to rebind to another host even while you attempt to find out if the <code>ypset</code> operation succeeded. For example, you can type:</p> <pre>example% ypset host1 example% ypwhich host2</pre> <p>which can be confusing. This is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when <i>host1</i> does not respond to <code>ypbind</code> because it is not running <code>ypserv</code> (or is overloaded), and <i>host2</i>, running <code>ypserv</code>, gets the binding.</p> <p><i>server</i> indicates the NIS server to bind to, and must be specified as a name or an IP address. This will work only if the node has a current valid binding for the domain in question, and <code>ypbind</code> has been set to allow use of <code>ypset</code>. In most cases, <i>server</i> should be specified as an IP address.</p> <p><code>ypset</code> tries to bind over a connectionless transport. The NIS library call, <code>yp_all()</code>, uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by <code>ypset</code>.</p> <p>Refer to <code>ypfiles(4)</code> for an overview of the NIS name service.</p>				
OPTIONS	<table><tr><td><code>-d <i>ypdomain</i></code></td><td>Use <i>ypdomain</i>, instead of the default domain.</td></tr><tr><td><code>-h <i>host</i></code></td><td>Set <code>ypbind</code>'s binding on <i>host</i>, instead of locally. <i>host</i> must be specified as a name.</td></tr></table>	<code>-d <i>ypdomain</i></code>	Use <i>ypdomain</i> , instead of the default domain.	<code>-h <i>host</i></code>	Set <code>ypbind</code> 's binding on <i>host</i> , instead of locally. <i>host</i> must be specified as a name.
<code>-d <i>ypdomain</i></code>	Use <i>ypdomain</i> , instead of the default domain.				
<code>-h <i>host</i></code>	Set <code>ypbind</code> 's binding on <i>host</i> , instead of locally. <i>host</i> must be specified as a name.

ypstart(1M)

- NAME** ypstart, ypstop – Start and stop NIS services
- SYNOPSIS** `/usr/lib/netsvc/yp/ypstart`
`/usr/lib/netsvc/yp/ypstop`
- DESCRIPTION** The `ypstart` command is used to start the Network Information Service (NIS). Once the host has been configured using the `ypinit(1M)` command, `ypstart` automatically determines the NIS status of the machine and starts the appropriate daemons.
- The `ypstop` command is used to stop the Network Information Service (NIS).
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

- NOTES** The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

NAME	ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C <i>tid prog server</i>] [-d <i>ypdomain</i>] [-h <i>host</i>] [-s <i>ypdomain</i>] <i>mapname</i></code>
DESCRIPTION	<p>The <code>ypxfr</code> command moves a NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory <code>/var/yp/<i>ypdomain</i></code> (this directory must already exist; <i>ypdomain</i> is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real <i>name</i>.</p> <p>If run interactively, <code>ypxfr</code> writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file <code>/var/yp/ypxfr.log</code> exists, it appends all its output to that file. Since <code>ypxfr</code> is most often run from the privileged user's <code>crontab</code> file, or by <code>ypserv</code>, the log file can be used to retain a record of what was attempted, and what the results were.</p> <p>For consistency between servers, <code>ypxfr</code> should be run periodically for every map in the NIS data base. Different maps change at different rates: a map may not change for months at a time, for instance, and may therefore be checked only once a day. Some maps may change several times per day. In such a case, you may want to check hourly for updates. A <code>crontab(1)</code> entry can be used to perform periodic updates automatically. Rather than having a separate <code>crontab</code> entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in <code>/usr/sbin/yp</code>: <code>ypxfr_1perday</code>, <code>ypxfr_2perday</code>, and <code>ypxfr_1perhour</code>. They can serve as reasonable first cuts.</p> <p>Refer to <code>ypfiles(4)</code> for an overview of the NIS name service.</p>
OPTIONS	<p><code>-c</code> Do not send a "Clear current map" request to the local <code>ypserv</code> process. Use this flag if <code>ypserv</code> is not running locally at the time you are running <code>ypxfr</code>. Otherwise, <code>ypxfr</code> complains that it cannot talk to the local <code>ypserv</code>, and the transfer fails.</p> <p><code>-f</code> Force the transfer to occur even if the version at the master is not more recent than the local version.</p> <p><code>-C <i>tid prog server</i></code> This option is <i>only</i> for use by <code>ypserv</code>. When <code>ypserv</code> starts <code>ypxfr</code>, it specifies that <code>ypxfr</code> should call back a <code>yppush</code> process at the host <i>server</i>, registered as program number <i>prog</i>, and waiting for a response to transaction <i>tid</i>.</p> <p><code>-d <i>ypdomain</i></code> Specify a domain other than the default domain.</p> <p><code>-h <i>host</i></code> Get the map from <i>host</i>, regardless of what the map says the master is. If <i>host</i> is not specified, <code>ypxfr</code> asks the</p>

ypxfr(1M)

NIS service for the name of the master, and try to get the map from there. *host* must be a name.

-s ypdomain Specify a source domain from which to transfer a map that should be the same across domains.

- FILES**
- `/var/yp/ypxfr.log`
log file
 - `/usr/lib/netsvc/yp/ypxfr_1perday`
script to run one transfer per day, for use with `cron(1M)`
 - `/usr/lib/netsvc/yp/ypxfr_2perday`
script to run two transfer per day, for use with `cron(1M)`
 - `/usr/lib/netsvc/yp/ypxfr_1perhour`
script for hourly transfers of volatile maps
 - `/var/yp/ypdomain`
NIS domain
 - `/usr/spool/cron/crontabs/root`
privileged user's crontab file

NAME	zdump – time zone dumper				
SYNOPSIS	zdump [-v] [-c <i>cutoffyear</i>] [<i>zonename</i> ...]				
DESCRIPTION	<p>The zdump command prints the current time for each timezone (<i>zonename</i>) listed on the command line. Specify <i>zonename</i> as the name of the timezone database file relative to <code>/usr/share/lib/zoneinfo</code>.</p> <p>Specifying an invalid timezone (<i>zonename</i>) to zdump does not return an error, rather zdump uses GMT. This is consistent with the behavior of the library calls; zdump reflects the same behavior of the time routines in <code>libc</code>. See <code>ctime(3C)</code> and <code>mktime(3C)</code>.</p>				
OPTIONS	<p>The following options are supported:</p> <p>-v Displays the entire contents of the timezone database file for <i>zonename</i>. Prints the time at the lowest possible time value, the time one day after the lowest possible time value, the times both one second before and exactly at each time at which the rules for computing local time change, the time at the highest possible time value, and the time at one day less than the highest possible time value. See <code>mktime(3C)</code> and <code>ctime(3C)</code> for information regarding time value (<i>time_t</i>). Each line of output ends with <code>isdst=1</code> if the given time is Daylight Saving Time or <code>isdst=0</code> otherwise.</p> <p>-c <i>cutoffyear</i> Cuts off the verbose output near the start of the year <i>cutoffyear</i>.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
FILES	<code>/usr/share/lib/zoneinfo</code> standard zone information directory				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

zic(1M)

NAME	zic – time zone compiler																		
SYNOPSIS	zic [-s] [-v] [-l <i>localtime</i>] [-p <i>posixrules</i>] [-d <i>directory</i>] [-y <i>yearistype</i>] [<i>filename...</i>]																		
DESCRIPTION	<p>zic reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a <i>filename</i> is '-', the standard input is read.</p> <p>Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment and extends to the end of the line. White space characters and pound signs may be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.</p>																		
Rule	<p>A rule line has the form:</p> <p>For example:</p> <pre>Rule NAME FROM TO TYPE IN ON AT SAVE LETTER/S</pre> <p>The fields that make up a rule line are:</p> <pre>Rule USA 1969 1973 - Apr lastSun 2:00 1:00 D</pre> <table><tr><td>NAME</td><td> Gives the (arbitrary) name of the set of rules this rule is part of.</td></tr><tr><td>FROM</td><td> Gives the first year in which the rule applies. The word <i>minimum</i> (or an abbreviation) means the minimum year with a representable time value. The word <i>maximum</i> (or an abbreviation) means the maximum year with a representable time value.</td></tr><tr><td>TO</td><td> Gives the final year in which the rule applies. In addition to <i>minimum</i> and <i>maximum</i> (as above), the word <i>only</i> (or an abbreviation) may be used to repeat the value of the FROM field.</td></tr><tr><td>TYPE</td><td> Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'-'</td><td> The rule applies in all years between FROM and TO inclusive.</td></tr><tr><td>uspres</td><td> The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td> The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td> The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td> The rule applies to odd-numbered years.</td></tr></table></td></tr></table>	NAME	Gives the (arbitrary) name of the set of rules this rule is part of.	FROM	Gives the first year in which the rule applies. The word <i>minimum</i> (or an abbreviation) means the minimum year with a representable time value. The word <i>maximum</i> (or an abbreviation) means the maximum year with a representable time value.	TO	Gives the final year in which the rule applies. In addition to <i>minimum</i> and <i>maximum</i> (as above), the word <i>only</i> (or an abbreviation) may be used to repeat the value of the FROM field.	TYPE	Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'-'</td><td> The rule applies in all years between FROM and TO inclusive.</td></tr><tr><td>uspres</td><td> The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td> The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td> The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td> The rule applies to odd-numbered years.</td></tr></table>	'-'	The rule applies in all years between FROM and TO inclusive.	uspres	The rule applies in U.S. Presidential election years.	nonpres	The rule applies in years other than U.S. Presidential election years.	even	The rule applies to even-numbered years.	odd	The rule applies to odd-numbered years.
NAME	Gives the (arbitrary) name of the set of rules this rule is part of.																		
FROM	Gives the first year in which the rule applies. The word <i>minimum</i> (or an abbreviation) means the minimum year with a representable time value. The word <i>maximum</i> (or an abbreviation) means the maximum year with a representable time value.																		
TO	Gives the final year in which the rule applies. In addition to <i>minimum</i> and <i>maximum</i> (as above), the word <i>only</i> (or an abbreviation) may be used to repeat the value of the FROM field.																		
TYPE	Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'-'</td><td> The rule applies in all years between FROM and TO inclusive.</td></tr><tr><td>uspres</td><td> The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td> The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td> The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td> The rule applies to odd-numbered years.</td></tr></table>	'-'	The rule applies in all years between FROM and TO inclusive.	uspres	The rule applies in U.S. Presidential election years.	nonpres	The rule applies in years other than U.S. Presidential election years.	even	The rule applies to even-numbered years.	odd	The rule applies to odd-numbered years.								
'-'	The rule applies in all years between FROM and TO inclusive.																		
uspres	The rule applies in U.S. Presidential election years.																		
nonpres	The rule applies in years other than U.S. Presidential election years.																		
even	The rule applies to even-numbered years.																		
odd	The rule applies to odd-numbered years.																		

If `TYPE` is something else, then `zic` will attempt to execute the command

```
yearistype year type
```

to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The `yearistype` command is not currently provided in the Solaris environment.)

IN	Names the month in which the rule takes effect. Month names may be abbreviated.										
ON	<p>Gives the day on which the rule takes effect. Recognized forms include:</p> <table> <tr> <td>5</td> <td>the fifth day of the month</td> </tr> <tr> <td>lastSun</td> <td>the last Sunday in the month</td> </tr> <tr> <td>lastMon</td> <td>the last Monday in the month</td> </tr> <tr> <td>Sun>=8</td> <td>first Sunday on or after the eighth</td> </tr> <tr> <td>Sun<=25</td> <td>last Sunday on or before the 25th</td> </tr> </table> <p>Names of days of the week may be abbreviated or spelled out in full. Note: There can not be spaces within the ON field.</p>	5	the fifth day of the month	lastSun	the last Sunday in the month	lastMon	the last Monday in the month	Sun>=8	first Sunday on or after the eighth	Sun<=25	last Sunday on or before the 25th
5	the fifth day of the month										
lastSun	the last Sunday in the month										
lastMon	the last Monday in the month										
Sun>=8	first Sunday on or after the eighth										
Sun<=25	last Sunday on or before the 25th										
AT	<p>Gives the time of day at which the rule takes effect. Recognized forms include:</p> <table> <tr> <td>2</td> <td>time in hours</td> </tr> <tr> <td>2:00</td> <td>time in hours and minutes</td> </tr> <tr> <td>15:00</td> <td>24-hour format time (for times after noon)</td> </tr> <tr> <td>1:28:14</td> <td>time in hours, minutes, and seconds</td> </tr> </table> <p>Any of these forms may be followed by the letter <code>w</code> if the given time is local "wall clock" time; <code>s</code> if the given time is local "standard" time; or <code>u</code> (or <code>g</code> or <code>z</code>) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.</p>	2	time in hours	2:00	time in hours and minutes	15:00	24-hour format time (for times after noon)	1:28:14	time in hours, minutes, and seconds		
2	time in hours										
2:00	time in hours and minutes										
15:00	24-hour format time (for times after noon)										
1:28:14	time in hours, minutes, and seconds										
SAVE	Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the AT field (without the <code>w</code> and <code>s</code> suffixes).										
LETTER/S	Gives the "variable part" (for example, the "S" or "D" in "EST" or "EDT" of time zone abbreviations to be used when this rule is in effect. If this field is '-', the variable part is null.										

Zone A zone line has the form:

zic(1M)

```
Zone  NAME                      GMTOFF  RULES/SAVE  FORMAT  [UNTIL]
```

For example:

```
Zone  Australia/SouthWest  9:30    -          CST     1992 Mar 15 12:00
      8:30    Aus     CST
```

The fields that make up a zone line are:

NAME	The name of the time zone. This is the name used in creating the time conversion information file for the zone.
GMTOFF	The amount of time to add to GMT to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign if time must be subtracted from GMT.
RULES/SAVE	The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '-' then standard time always applies in the time zone.
FORMAT	The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes.
UNTIL	The time at which the GMT offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given GMT offset and rule change until the time specified. The next line must be a "continuation" line; this has the same form as a zone line except that the string "Zone" and the name are omitted, as the continuation line will place information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines may contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link A link line has the form:

```
Link  LINK-FROM  LINK-TO
```

For example:

```
Link  US/Eastern  EST5EDT
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.

Except for continuation lines, lines may appear in any order in the input.

- OPTIONS**
- d *directory* Create time conversion information files in the directory *directory* rather than in the standard directory `/usr/share/lib/zoneinfo`.
 - l *localtime* Use the given time zone as local time *localtime*. zic will act as if the file contained a link line of the form:

Link *localtime* *localtime*
 - p *posixrules* Use the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. zic will act as if the input contained a link line of the form

Link *posixrules* *posixrules*
- This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.
- s Limit time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.
 - v Complain if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. GMT, January 1, 1970, to 3:14:07 a.m. GMT, January 19, 2038).
 - y *yearistype* Use the given command *yearistype* rather than `yearistype` when checking year types (see Rules under DESCRIPTION).

OPERANDS *filename* A file containing input lines that specify the time conversion information files to be created. If a *filename* is '-', the standard input is read.

FILES `/usr/share/lib/zoneinfo` standard directory used for created files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `time(1)`, `zdump(1M)`, `ctime(3C)`, `mktime(3C)`, `attributes(5)`

NOTES For areas with more than two types of local time, you may need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

zic(1M)

Index

Numbers and Symbols

- mount_xmemfs, 861
- projadd, 1094
- ab2admin(1M) — AnswerBook2 Administration, 28
- construct a udfs file system — mkfs_udfs, 807
- 24-bit TrueColor Visual for OpenWindows with an S24 frame buffer system (TCX) — texconfig
- configure the default linearity, 1441

A

- ab2admin — command-line interface for AnswerBook2 administration, 28
- ab2cd — run AnswerBook2 server from the Documentation CD, 33
- ab2regsvr — register an AnswerBook2 document server with FNS (Federated Naming Service), 37
- accept — accept print requests, 38
- access system administration tools with a graphical user interface — solstice, 1372
- accounting
 - run daily — runacct, 1195
- accounting commands
 - acctcms, 46
 - acctcon, 48
 - acctdisk, 40
 - acctdusg, 40
 - acctmerg, 50

accounting commands (*continued*)

 - prctmp, 53
 - prdaily, 53
 - prtacct, 53
 - runacct, 53
 - shutacct, 53
 - startup, 53
 - turnacct, 53
- ## acct — miscellaneous accounting commands, 40
- acctcms — command summary from process accounting records, 46
 - acctcon — create summary of connect records, 48
 - acctcon1 — create summary of connect records, 48
 - acctcon2 — create summary of connect records, 48

acctdisk — create disk usage records, 40

acctdusg — compute disk usage by login, 40

acctmerg — merge or add total disk accounting files, 50

accton — turn on process accounting, 40

acctprc — summary of process accounting, 51

acctprc1 — summary of process accounting, 51

acctprc2 — summary of process accounting, 51

acctsh — shell procedures for accounting, 53

acctwtmp — create connect accounting record in /var/adm/wtmp, 40

adb scripts

- generate — adbgen, 56

adbgen — generate adb script, 56

add (create) a new group definition on the system — groupadd, 458

add a new device driver to the system — add_drv, 61

add_drv — add a new device driver to the system, 61

addbadsec — map out defective disk blocks, 59

address resolution display and control — arp, 82

adds an application to the Solstice application registry — soladdapp, 1370

administer a new role account on the system — roleadd, 1150

administer disk space used for caching file systems with the Cache File-System (CacheFS) — cfsadmin, 205

administer files available as block devices through lofi — lofiadm, 661

administer NIS+ aliases — aliasadm, 75

administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices — luxadm, 738

admintool — system administration tool with a graphical interface, 65

afbconfig — configure the AFB Graphics Accelerator, 67

aliasadm — administer NIS+ aliases, 75

allocate — allocate devices, 77

ancillary agent for inbound zone transfers — named-xfer, 868

AnswerBook

- TOC documentation— ab2admin(1M), 28

answerbook2_admin — bring up AnswerBook2 administration tool GUI, 79

AnswerBook2 administration tool GUI — answerbook2_admin, 79

apply a patch package to a Solaris 2 system — patchadd, 990

arp — address resolution display and control, 82

ASET

- monitors or restricts accesses to system files and directories — aset, 84
- prints tasks status — taskstat, 1440

aset.restore — restore files and directories to the state before ASET was installed, 90

aspppd — asynchronous PPP link manager, 91

- Authentication, 93
- Configuration File, 93
- Interfaces, 92
- Keywords, 94
- Path, 92
- Routing, 92

aspppls — asynchronous PPP link manager, 91

asynchronous PPP link manager

- aspppd, 91
- aspppls, 91

audit — maintain audit trail, 100

audit records

- select or merge from audit trail files — auditreduce, 106

audit_startup shell script, 114

audit statistics report — auditstat, 115

audit trail file

- select records from — auditreduce, 106

audit_warn — audit daemon warning script, 117

auditconfig — get and set kernel audit parameters, 101

auditd — audit daemon, 104

auditreduce — select or merge audit records from audit trail files, 106

auditstat — display kernel audit statistics, 115

autoboot procedures — boot, 556

autofs
 automatically mount file systems —
 automount, 119

Autofs
 mount/unmount request server —
 automountd, 126

Automated conversational exchange tool —
 chat, 211

Automated Security Enhancement Tool, *See*
 ASET

automount — automatically mount file
 systems, 119

automountd — Autofs mount/unmount
 request server, 126

autopush — configures lists of automatically
 pushed STREAMS modules, 127

B

backup NIS+ directories — nisbackup, 913

Basic Security Module
 enable — bsmconv, bsmunconv, 145

Basic Security Module commands
 — audit, 100
 — audit_startup, 114
 — audit_warn, 117
 — auditconfig, 101
 — auditd, 104
 — auditreduce, 106
 — auditstat, 115

bdconfig — configures the bd (buttons and
 dials) stream, 129

boot — bootstrap procedures, 131

boot parameter server —
 rpc.bootparamd, 1166

boot — system startup procedures, 556

BOOTP
 DHCP network table management utility —
 pntadm, 1042
 administration — dhtadm, 295
 server — in.dhcpd, 493
 service — dhcpconfig, 286

bootstrap procedures — boot, 556

bootstrap PROM monitor program —
 monitor, 819

Bootstrap Protocol, *See* 'DHCP'

Bourne shell
 — rsh, 1192

broadcast message
 network wall server — rpc.rwalld, 1181
 write to all users — wall, 1503
 write to all users of a group — wall, 1503
 write to all users over a network —
 rwall, 1198

bsmconv — enable Solaris system to use Basic
 Security Module, 145

bsmunconv — enable Solaris system to use Basic
 Security Module, 145

busstat — report bus-related performance
 statistics, 146

C

C compiler
 create a front-end to cc command —
 gcc, 446

cachefs
 cachefslog — Cache File System
 logging, 150
 cachefsstat — Cache File System
 statistics, 154
 cachefswssize — Determine working set size
 for cachefs, 156
 cfsadmin — administer disk space used for
 caching file systems with the Cache
 File-System (CacheFS), 205
 fsck_cachefs — check integrity of data
 cached with CacheFS, 403
 mount_cachefs — mount CacheFS file
 systems, 836

cachefspack — pack files and file systems in the
 cache, 152

captainfo — convert termcap description to
 terminfo description, 158

catman — create formatted files for manual
 pages, 159

CD-ROM
 packages on — pkgadd, 1024

CD-ROM, managing
 — rmmount, 1146

CD-ROM, mounting
 — rmmount, 1146
 cfgadm — configuration administration, 163
 cfgadm_ac — EXX00 memory system
 administration, 174
 cfgadm_scsi — SCSI hardware specific
 commands for cfgadm, 195
 cfgadm_sysctrl — EXX00 system board
 administration, 201
 cfs, *See* cachefs
 cfsadmin — administer disk space used for
 caching file systems with the Cache
 File-System (CacheFS), 205
 CacheFS Resource Parameters, 206
 cg14config — configure the cgfourteen
 device, 209
 change processor operational status —
 psradm, 1113
 chargefee — accounting shell procedure, 53
 chat — Automated conversational exchange
 tool, 211
 check-hostname — check if sendmail can
 determine the system's fully-qualified host
 name, 219
 check if sendmail can determine the system's
 fully-qualified host name —
 check-hostname, 219
 check integrity of data cached with CacheFS —
 fsck_cachefs, 403
 check-permissions — check permissions on mail
 rerouting files, 220
 check permissions on mail rerouting files —
 check-permissions, 220
 chown — change owner of file, 221
 chroot — change root directory for a
 command, 222
 CIM Boot Manager
 starting, 521
 CIM Object Manager
 stopping, 521
 ckpacct — accounting shell procedure, 53
 clear inode
 — clri, 227
 — dcopy, 227
 clear_locks — clear locks held on behalf of an
 NFS client, 225
 clear locks held on behalf of an NFS client —
 clear_locks, 225
 client configuration daemon — dhcpagent, 282
 clinfo — display cluster information, 226
 closewtmp — puts a false DEAD_PROCESS
 record in /var/adm/wtmpx file, 40
 clri — clear inode, 227
 command-line interface for AnswerBook2
 administration — ab2admin, 28
 compile MOF files into CIM classes —
 mofcomp, 816
 configuration applications
 execute or define — sysidconfig, 1425
 configure the AFB Graphics Accelerator —
 afbconfig, 67
 configure the FFB Graphics Accelerator —
 ffbconfig, 352
 configure the M64 Graphics Accelerator —
 m64config, 753
 configure the PGX32 Graphics Accelerator —
 pgxconfig, 1013
 configure the Raptor GFX Graphics Accelerator
 — GFXconfig, 1013
 configure
 cgfourteen device — cg14config, 209
 contiguous memory for sx video —
 sxconfig, 1407
 undo system configuration —
 sys-unconfig, 1434
 configure and administer a smartcard —
 smartcard, 1272
 configure device attributes — devconfig, 258
 configure Mobility IP Agent —
 mipagentconfig, 792
 configure operating system crash dump —
 dumpadm, 326
 configure or unconfigure mouse, keyboard,
 display — kdmconfig, 611
 Configure the power management system —
 pmconfig, 1040
 configure the Solaris Management Console —
 smccconf, 1289
 configure transport providers for use by sockets
 — soconfig, 1368
 configures the bd (buttons and dials) stream —
 bdconfig, 129

- connect accounting
 - acctcon, 48
 - fwtmp, 445
 - utmp2wtmp, 40
 - wtmpfix, 445
- consadm — select or display devices used as auxiliary console devices, 228
- construct a FAT file system — mkfs_pcfs, 803
- control and query bindings of processes to processors — pbind, 1006
- conv_lp — convert LP configuration, 230
- conv_lpd — convert LPD configuration, 231
- convert a JavaSpaces datastore to the newer Reliable Log datastore format —
 - wbemconfig, 1508
- convert LP configuration — conv_lp, 230
- convert LPD configuration — conv_lpd, 231
- convert name server configuration files —
 - named-bootconf, 867
- copy FNS contexts — fncopy, 373
- coradm — core file administration, 233
- core file administration — coradm, 233
- CPU PROM monitor
 - program — monitor, 819
- cpustat — monitor system behavior using CPU performance counters, 237
- crash — examine system memory image, 239
- create
 - NIS dbm file — makedbm, 760
- create an FNS context — fncreate, 375
- create FNS file system contexts —
 - fncreate_fs, 383
- create new printers in the FNS namespace —
 - fncreate_printer, 388
- creation and management of processor sets —
 - psrset, 1118
- cron — clock daemon, 245
- cvcd — virtual console daemon, 247

D

- daemon, distributed system administration —
 - sadmind, 1206
- daemon for DHCP client configuration —
 - dhcpageant, 282

- daemons
 - clock daemon — cron, 245
 - Internet Trivial File Transfer Protocol —
 - in.tftpd, 574
 - kernel statistics — rpc.rstatd, 1179
 - network router discovery daemon —
 - in.rdisc, 537
 - network username server —
 - rpc.rusersd, 1180
 - network wall server — rpc.rwall, 1181
 - network status monitor — statd, 1382
 - NFS — nfsd, 890
 - NIS+ service — rpc.nisd, 1171
 - remote shell server — in.rshd, 549
 - remote quota — rquotad, 1191
 - RPC-based remote execution —
 - rpc.rexd, 1177
 - server which records packets sent by spray —
 - rpc.sprayd, 1182
- date
 - set system date from a remote host —
 - rdate, 1136
- dcopy — clear inode, 227
- dd — convert and copy a file, 249
- deallocate — deallocate devices, 255
- debug tools
 - generate adb script — adbgen, 56
- delete a project from the system —
 - projdel, 1096
- delete a user's login from the system —
 - roledel, 1154
- destroy an FNS context — fndestroy, 391
- devattr — displays the values for a device's attributes, 257
- devconfig — configure device attributes, 258
- device access
 - verifies accessibility — getvol, 456
- device_maps
 - display entries — dminfo, 313
- devices
 - add, modify remove device entry from table —
 - putdev, 1122
 - add, remove and change device group table —
 - putdgrp, 1125
 - adds /dev entries for miscellaneous devices and pseudo-devices — devlinks, 264

devices (*continued*)

- adds /dev entries for tape drives attached to the system — tapes, 1436
- allocation — allocate, 77
- cgfourteen — configure the cgfourteen device, 209
- deallocation — deallocate, 255
- display access control entries from device_maps, 313
- display attributes — devattr, 257
- group list — getdgrp, 449
- list — getdev, 447
- list_devices — list_devices, 640
- lists members of a group — listdgrp, 642
- name — devnm, 268
- print information about disk devices — devinfo, 263
- print VTOC of a block device — prtvtoc, 1111
- release from exclusive use — devfree, 260
- remove a device driver from the system — rm_drv, 1139
- reserve for exclusive use — devfree, 269

/devices directory

- configure — drvconfig, 321

devinfo — print device specific information, 263

df — display amount of used and available disk space, 271

df_ufs — display amount of space occupied by ufs, 281

dfmounts — displays information on resources shared through DFS, 275

dfmounts_nfs — displays information on resources shared through NFS, 277

DFS

- display information on resources shared — dfmounts, 275
- list available resources from remote or local systems — dfshares, 278

dfshares — list available resources from remote or local systems, 278

dfshares_nfs — list available resources from remote systems, 279

DHCP

- network table management utility — pntadm, 1042

DHCP (*continued*)

- administration — dhtadm, 295
- server — in.dhcpd, 493
- service — dhcpconfig, 286

DHCP client configuration daemon — dhcpagent, 282

DHCP service lock daemon — dsvclockd, 323

dhcpagent — daemon for DHCP client configuration, 282

dhcpconfig — DHCP service configuration utility, 286

dhcpgmgr — graphical interface for managing DHCP service, 293

dhtadm — DHCP configuration table management utility, 295

Diffie-Hellman key pair, 889

directories

- move — mvdir, 866

disk accounting

- acctdisk, 40
- acctdusg, 40
- acctmerg, 50

disk blocks

- display free ones — df, 271

disk quotas

- remote quota daemon — rquotad, 1191

disk quotas and usage

- display for a user's ufs file system — quota, 1132

disk usage

- summary — du, 324

diskettes

- packages on — pkgadd, 1024

disks — adds /dev entries for hard disks attached to the system, 301

disks

- partitioning and maintenance utility — format, 395

diskscan — perform surface analysis, 305

display

- system configuration information — prtconf, 1104
- system diagnostic information — prtdiag, 1108

display cluster information — clinfo, 226

display kernel statistics — kstat, 621

- displays information about processors —
psrinfo, 1116
- Distributed File System, *See* DFS
- dmesg — create error log from system
diagnostic messages, 308
- dmi_cmd — DMI command line interface
utility, 309
- DMI command line interface utility —
dmi_cmd, 309
- DMI command line retrieval utility —
dmiget, 312
- dmiget — DMI command line retrieval
utility, 312
- dminfo — display device_maps entries, 313
- dmisspd — Sun Solstice Enterprise DMI Service
Provider, 315
- DoD Internet
host table — gettable, 453
- DoD Internet format host table, convert —
htable, 469
- dodisk — accounting shell procedure, 53
- domainname — display name of current
domain, 318
- domainname — set name of current
domain, 318
- dr_daemon — Enterprise 10000 Dynamic
Reconfiguration daemon, 319
- driver statistics from a synchronous serial link,
report — syncstat, 1417
- drvconfig — configure /devices, 321
- dsvclockd — DHCP service lock daemon, 323
- du — summarize disk usage, 324
- dumpadm — configure operating system crash
dump, 326
- Dynamic Host Configuration Protocol, *See*
'DHCP'

E

- edquota — edit user quotas for ufs file
system, 331
- EEPROM display and load program —
eprom, 333
- encryption keys
server for storing private keys —
keyserv, 618

- Enterprise 10000 Dynamic Reconfiguration
daemon — dr_daemon, 319
- environment variables
convert termcap description into terminfo
description — captainfo, 158
- error log
create from system diagnostic messages —
dmesg, 308
- EXX00 memory system administration —
cfgadm_ac, 174
- EXX00 system board administration —
cfgadm_sysctrl, 201

F

- fbconfig — Frame Buffer configuration
utility, 341
- fdetach — detach a name from STREAMS-based
file descriptor, 343
- fdisk — create or modify fixed disk partition
table
Menu Options, 344
- ffbconfig — configure the FFB Graphics
Accelerator, 352
- FIFO
make FIFO special file — mkfifo, 799
- FIFO, make — mknod, 812
- file system
cache file systems
See cachefs
- change the dynamic parameters —
tunefs, 1455
- check and repair — fsck, 399
- check and repair ufs — fsck_ufs, 412
- construct — mkfs, 801
- construct ufs — mkfs_ufs, 809
- create new — newfs, 885
- debugger — fsdb, 416
- display amount of used disk space occupied
by ufs — df_ufs, 281
- display amount of used and available disk
space — df, 271
- link and unlink files and directories —
link, 639
- list file names and statistics — ff, 349

file system (*continued*)

- list file names and statistics for ufs —
ff_ufs, 360
- loopback — mount, 831
- make literal copy — volcopy, 1498
- mount — mount, 831
- mount — mountall, 834
- mount ufs — mount_ufs, 858
- move directory — mvdir, 866
- provide labels — labelit, 626
- provide labels for ufs — labelit_ufs, 630
- report processes using file or file structure —
fuser, 443
- share multiple resources — shareall, 1256
- ufs, make image copy — volcopy_ufs, 1500
- unmount — umount, 831
- unmount — umountall, 834
- unshare multiple resources —
unshareall, 1256

file system consistency check and interactive —
fsck_pcfs, 404

file system consistency check and interactive
repair — fsck_s5fs, 406

file system type, determine — fstyp, 442

File Transfer Protocol
server — in.ftpd, 506

files

- change ownership — chown, 221
- convert and copy — dd, 249

firmware — bootable firmware programs and
firmware commands, 361

floppy, managing
— rmmount, 1146

floppy, mounting
— rmmount, 1146

flush disk activity — sync, 1410

fmthard — populate Volume Table of Contents
on hard disks, 369

fnccopy — copy FNS contexts, 373

fncreate — create an FNS context, 375

fncreate_fs — create FNS file system
contexts, 383

fncreate_printer — create new printers in the
FNS namespace, 388

fndestroy — destroy an FNS context, 391

FNS
copy FNS contexts — fnccopy, 373

FNS (*continued*)

- create context — fncreate, 375
- create FNS file system contexts —
fncreate_fs, 383
- select naming service for FNS Initial Context
— fnselect, 392

fnselect — select naming service for FNS Initial
Context, 392

format — disk partitioning and maintenance
utility, 395

Frame Buffer configuration utility —
fbconfig, 341

fsck_cachefs — check integrity of data cached
with CacheFS, 403

fsck — check and repair file systems, 399

fsck_pcfs — file system consistency check and
interactive, 404

fsck_s5fs — file system consistency check and
interactive repair, 406

fsck_ufs — check and repair ufs, 412

fsdb — file system debugger, 416

fsdb_ufs — ufs file system debugger, 425

- Commands, 428
- Expressions, 426
- Formatted Output, 431
- Inode Commands, 430

fsirand — install random inode generation
numbers, 434

fstyp — determine file system type, 442

FTP
daemon on remote host — in.ftpd, 506

fuser — identify processes using file or file
structure, 443

fwtmp — convert connect accounting records to
ASCII, 445

G

- gencc — create a front-end to cc
command, 446
- generate message IDs — msgid, 865
- get printer configuration — lpget, 691
- getdev — lists devices that match given
criteria, 447
- getdgrp — lists device groups which contain
devices that match given criteria, 449

getent — gets a list of entries from administrative databases, 451
 gettable — get DoD Internet host table, 453
 getty — set terminal type, modes, speed, and line discipline, 454
 getvol — verifies device accessibility, 456
 GFXconfig — configure the Raptor GFX Graphics Accelerator, 1013
 graphical interface for managing DHCP service — dhcpcmgr, 293
 group file
 check for inconsistencies — grpck, 1127
 groupadd — add (create) a new group definition on the system, 458
 groupdel — delete a group definition on the system, 460
 groupmod — modify a group definition on the system, 461

H

halt — stop the processor, 466
 hard disks
 populate Volume Table of Contents — fmthard, 369
 hostconfig — configure a system's host parameters, 467
 hsfs
 labels for hsfs file systems, provide and print — labelit_hfs, 628
 mount — mount_hfs, 840
 htable — convert DoD Internet format host table, 469

I

I/O statistics report — iostat, 578
 IA Network Booting RPL (Remote Program Load) Server — rpld, 1186
 ICMP
 router discovery daemon — in.rdisc, 537
 id — return user identity, 470
 ifconfig — configure network interface parameters, 473
 in.comsat — biff server, 492

in.dhcpd — DHCP server, 493
 in.fingerd — remote user information server, 501
 in.ftpd — File Transfer Protocol daemon on remote host, 506
 in.lpd — print job listener, 523
 in.rarpd — Reverse Address Resolution Protocol server, 535
 in.rdisc — ICMP router discovery daemon, 537
 in.rexecd — remote execution server, 539
 in.ripngd — network routing daemon for IPv6, 541
 in.rlogind — remote login server, 544
 in.routed — network routing daemon, 546
 in.rwhod — system status server, 552
 in.talkd — talk server, 570
 in.telnetd — DARPA TELNET virtual terminal protocol server, 571
 in.tftpd — Internet Trivial File Transfer Protocol server, 574
 in.tnamed — DARPA trivial name server, 575
 in.uucpd — UUCP server, 576
 incremental file system dump —
 ufsdump, 1458
 inetd — Internet services daemon, 499
 init — process control initialization, 516
 /etc/defaults/init file, 517
 init and System Booting, 516
 inittab Additions, 517
 Run Level Changes, 517
 Run Level Defined, 516
 telinit, 518
 init.wbem — start CIM Boot Manager, 521
 init.wbem — stop CIM Object Manager, 521
 initialize LDAP client machine or create an LDIF of an LDAP client profile —
 ldapclient, 633
 initialize LDAP client machine or create an LDIF of an LDAP client profile —
 ldap_gen_profile, 633
 inode
 clear — clri, 227
 install — install commands, 554
 install
 SunOS/SVR4 — suninstall, 1394
 installboot procedures — boot, 556

installer — Solaris Web Start installer utility, 558
 installf — add a file to software installation database, 559
 Internet
 biff server — in.comsat, 492
 DARPA TELNET virtual terminal protocol server — in.telnetd, 571
 DARPA trivial name server — in.tnamed, 575
 DHCP server — in.dhcpd, 493
 DHCP service configuration — dhcpconfig, 286
 File Transfer Protocol daemon on remote host — in.ftpd, 506
 ICMP router discovery daemon — in.rdisc, 537
 network routing daemon — in.routed, 546
 query domain name servers — nslookup, 957
 query domain name servers — nstest, 966
 RARP server — in.rarpd, 535
 remote user information server — in.fingerd, 501
 send ICMP ECHO_REQUEST packets to network hosts — ping, 1020
 server for talk program — in.talkd, 570
 services daemon — inetd, 499
 system status server — in.rwhod, 552
 Trivial File Transfer Protocol server — in.tftpd, 574
 Internet Control Message Protocol, *See* ICMP
 Internet Protocol
 to Ethernet addresses — arp, 82
 Interprocess Communication
 make FIFO special file — mkfifo, 799
 iostat — report I/O statistics, 578
 ipseckey — manually manipulate an IPsec Security Association Database (SABD), 596

K

kadb — a kernel debugger, 605
 kdmconfig — configure or unconfigure keyboard, display, and mouse options, 611

Kerberos authentication tickets
 generate and validate for kernel RPC — kerbd, 614
 Kerberos warning daemon — ktk_t_warnd, 625
 kernel — UNIX system executable file containing basic operating system services, 615
 kernel
 debugger — kadb, 605
 display status of loaded modules — modload, 813
 load a module — modload, 814
 kernel — UNIX system executable file containing basic operating system services SPARC Only, 615, 617
 kernel
 unload a module — modunload, 815
 kernel debugger — kadb, 605
 Kernel Symbolic Debugging for OpenBoot Firmware — obpsym, 984
 kernel system event notification daemon — syseventd, 1423
 keyserv — server for storing private encryption keys, 618
 killall — kill all active processes, 620
 kstat — display kernel statistics, 621
 ktk_t_warnd — Kerberos warning daemon, 625

L

labelit — provide labels for file systems, 626
 labelit_hfs — provide and print labels for hfs file systems, 628
 labelit_ufs — provide labels for ufs, 630
 lastlogin — accounting shell procedure, 53
 ldap_gen_profile — initialize LDAP client machine or create an LDIF of an LDAP client profile, 633
 ldapclient — initialize LDAP client machine or create an LDIF of an LDAP client profile, 633
 link — link and unlink files and directories, 639
 list_devices — list_devices, 640
 listdgrp — lists members of a device group, 642

listen — network listener daemon, 643

llc2_loop — loopback diagnostics to test the driver, adapter and network., 645

lock

- lockstat, 653

lockd — network lock daemon, 649

lockfs — lock file system, 650

lockstat — report kernel lock and profiling statistics, 653

lofiadm — administer files available as block devices through lofi, 661

log files and system log daemon — syslogd, 1431

logins — list user and system login information, 665

loopback diagnostics to test the driver, adapter and network. — llc2_loop, 645

loopback file system

- mount — mount, 831

LP print services

- administer filters — lpfilter, 679
- administer forms — lpforms, 684
- configure — lpadmin, 667
- register remote systems — lpsystem, 699
- set printing queue priorities — lpusers, 700

lpadmin — configure LP print service, 667

lpfilter — administer filters used with LP print service, 679

lpforms — administer forms used with LP print service, 684

lpforms — administer forms used with the LP print service

- Adding or Changing a Form, 684
- Allowing and Denying Access to a Form, 687

lpforms — administer forms used with the LP print service

- Deleting a Form, 686

lpforms — administer forms used with the LP print service

- Listing Form Attributes, 687
- Listing the Current Alert, 689
- Removing an Alert Definition, 689
- Setting an Alert to Mount a Form, 687
- Terminating an Active Alert, 689

lpget — get printer configuration, 691

lpmove — moves print requests that are queued, 693

lpsched — start the LP print service, 695

lpset — set printing configuration, 696

lpshut — stop the LP print service, 698

lpsystem — register remote systems with LP print service, 699

lpusers — set printing queue priorities, 700

lucreate, 711

lumount — mount or unmount all file systems in a boot environment, 725

luumount — mount or unmount all file systems in a boot environment, 725

luupgrade, 731

luxadm — administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices, 738

luxadm — administration program for the Sun Enterprise Network Array (SENA), RSM and SPARCstorage Array (SSA) subsystems

- Enclosure, 740
- Enclosure Services Card Subcommands, 748
- Other Expert Mode Subcommands, 749
- Pathname, 738
- SENA Expert Mode Subcommands, 748
- SPARCstorage Array Subcommands, 747
- Subcommands, 740
- usr/sbin, 752

M

m64config — configure the M64 Graphics Accelerator, 753

mail delivery server — sendmail, 1234

mail.local — store mail in a mailbox, 758

mail utilities

- biff server — in.comsat, 492

make FIFO — mknod, 812

make FIFO special file — mkfifo, 799

make local NFS file systems available for mounting by remote systems — share_nfs, 1257

make named pipe — mkfifo, 799

make named pipe — mknod, 812

make special file — mknod, 812

makedbm — make NIS ndbm file, 760
 manage bulk operations on user accounts —
 smmultiuser, 1320
 manage diskless client support for a server —
 smdiskless, 1302
 manage email alias entries — smmaillist, 1316
 manage entries in the exec_attr database —
 smexec, 1308
 manage group entries — smgroup, 1312
 manage jobs in the crontab database —
 smcron, 1296
 manage OS services — smoservice, 1325
 manage profiles in the prof_attr and exec_attr
 databases — smprofile, 1331
 manage roles and users in role accounts —
 smrole, 1337
 manage user entries — smuser, 1345
 manual pages
 create formatted files for — catman, 159
 manually manipulate an IPsec Security
 Association Database (SABD) —
 ipseckey, 596
 map out defective disk blocks —
 addbadsec, 59
 mibiisa — Sun SNMP Agent, 766
 mipagent — Mobile IP agent, 790
 mipagentconfig — configure Mobility IP
 Agent, 792
 mipagentstat — show Mobile IP Mobility Agent
 status, 797
 mkfifo — make FIFO special file, 799
 mkfile — create a file, 800
 mkfs — make file system, 801
 mkfs_pcfs — construct a FAT file system, 803
 mkfs_udfs — construct a udfs file system, 807
 mkfs_ufs — construct ufs, 809
 mknod — make special file, 812
 Mobile IP agent — mipagent, 790
 modify a project's information on the system —
 projmod, 1097
 modify a role's login information on the system
 — rolemod, 1156
 modinfo — display status of loaded kernel
 modules, 813
 modload — load a kernel module, 814
 modunload — unload a kernel module, 815

mofcomp — compile MOF files into CIM
 classes, 816
 monacct — accounting shell procedure, 53
 monitor program — monitor, 819
 monitor system behavior using CPU
 performance counters — cpustat, 237
 mount — mount filesystems and remote
 resources, 831
 mount or unmount all file systems in a boot
 environment — lumount, 725
 mount or unmount all file systems in a boot
 environment — luumount, 725
 mount
 show all remote mounts —
 showmount, 1265
 mount_cachefs — mount CacheFS file
 systems, 836
 mount_hfs — mount hfs file systems, 840
 mount_hfs file systems — mount_hfs, 840
 mount_nfs — mount remote NFS
 resources, 842
 mount_pcfs — mount pcfs file systems, 851
 mount_pcfs file systems — mount_pcfs, 851
 mount_s5 file systems — mount_s5fs, 853
 mount_s5fs — mount s5 file systems, 853
 mount_tmpfs — mount tmpfs, 855
 mount_ufs — mount ufs, 858
 mount_xmemfs —, 861
 mountall — mount multiple filesystems, 834
 mountd — NFS mount request server, 839
 mouse, keyboard, display
 configure or unconfigure — kdmconfig, 611
 mpstat — report per-processor statistics, 863
 msgid — generate message IDs, 865
 mvdir — move a directory, 866

N

name service cache daemon — nscd, 955
 named-bootconf — convert name server
 configuration files, 867
 named pipe, make — mkfifo, 799
 named pipe, make — mknod, 812
 named-xfer — ancillary agent for inbound zone
 transfers, 868

ncaconfd — Solaris Network Cache and Accelerator (NCA) configuration daemon, 870
 ncad — Solaris Network Cache and Accelerator (NCA) door server daemon, 871
 ncheck — generate a list of path names vs i-numbers of all files on special, 872
 ncheck_ufs — generate a list of pathnames vs i-numbers for ufs, 874
 ndd — get and set driver configuration parameters, 877
 netstat — show network status, 879
 netstat — display network status
 Active Sockets (First Form), 880
 DHCP Interface Information (Sixth Form), 883
 Interface Status (Third Form), 882
 Multicast Routing Tables (Fifth Form), 883
 Network Data Structures (Second Form), 881
 Routing Table (Fourth Form), 882
 TCP Sockets, 881
 network routing daemon — in.routed, 546
 network
 listener daemon — listen, 643
 lock daemon — lockd, 649
 test connections to hosts using ICMP — ping, 1020
 Network File System, *See* NFS
 network interface parameters
 configure — ifconfig, 473
 network listener service
 administration — nlsadmin, 949
 network packets capture and inspection — snoop, 1357
 network routing daemon for IPv6 — in.ripngd, 541
 Network Time Protocol daemon — xntpd, 1520
 newfs — make new file system, 885
 newkey — create a new key in publickey database, 889
 NFS
 crash and recovery functions for locking services — statd, 1382
 create files for use as NFS mounted swap areas — mkfile, 800
 NFS (*continued*)
 daemon — nfsd, 890
 display information on resources shared — dfmounts_nfs, 277
 display statistics — nfsstat, 895
 list available resources from remote systems — dfshares_nfs, 279
 make local NFS filesystem unavailable for mounting by remote systems — unshare_nfs, 1473
 mount — mount_nfs, 842
 mount request server — mountd, 839
 NFS, secure
 create a new key in publickey database — newkey, 889
 NFS security
 server for storing private encryption keys — keyserve, 618
 nfsstat — display NFS statistics, 895
 NIS
 binder process — ypbind, 1544
 make ndbm file — makedbm, 760
 point binder process ypbind at a particular server — ypset, 1554
 rebuild database — ypmake, 1547
 return current version of a NIS map at a NIS server host — yppoll, 1548
 transfer NIS map from a NIS server to host — ypxfr, 1557
 NIS+
 add /etc files and NIS maps into their corresponding NIS+ tables — nisaddent, 906
 client and root server initialization utility — nisinit, 922
 credential creation tool — nisaddcred, 900
 display the contents of the NIS+ transaction log — nislog, 926
 initialize a domain to store system administration information— nissetup, 943
 nisping — ping NIS+ servers, 927
 nissetup — initialize a NIS+ domain to serve clients, 943
 nisstat — report NIS+ server statistics, 945
 service daemon — rpc.nisd, 1171

NIS+ (*continued*)

- update public keys in NIS+ directory object
 - nisupdkeys, 947
- utility to cache location information about NIS+ servers — nis_cachemgr, 916
- utility to print out the contents of the shared cache file — nisshowcache, 944

NIS+ credentials for NIS+ principals

- initialize — nisclient, 918

NIS+ password update daemon

- nispasswd, 1175
- rpc.nispasswd, 1175

NIS+ servers

- set up — nisserver, 940

NIS+ utility to set server preferences for NIS+ clients — nisprefadm, 933

NIS server and binder processes

- ypserv, 1551
- ypxfrd, 1551

NIS services, start

- ypstart, 1556

NIS services, stop

- ypstop, 1556

nisaddcred — create NIS+ credentials, 900

nisaddent — add /etc files and NIS maps into their corresponding NIS+ tables, 906

nisbackup — backup NIS+ directories, 913

nisclient — initialize NIS+ credentials for NIS+ principals, 918

nispasswd — NIS+ password update daemon, 1175

nisping — ping NIS+ servers, 927

nispopulate — populate the NIS+ tables in a NIS+ domain, 929

nisprefadm — NIS+ utility to set server preferences for NIS+ clients, 933

nisrestore — restore NIS+ directory backup, 937

nisserver — set up NIS+ servers, 940

nissetup — initialize a domain to serve clients, 943

nisshowcache — NIS+ utility to print out the contents of the shared cache file, 944

nisstat — report NIS+ server statistics, 945

nscd — name service cache daemon, 955

nslookup — query Internet domain name servers, 957

nstest — query Internet domain name servers, 966

nsupdate — update Internet name servers interactively, 970

ntpdate — set the date and time by way of NTP, 973

ntpq — standard Network Time Protocol query program, 976

- Control Message Commands, 978
- Interactive Commands, 977

ntptrace — trace a chain of NTP hosts back to their master time source, 983

nulladm — accounting shell procedure, 53

O

obpsym — Kernel Symbolic Debugging for OpenBoot Firmware, 984

- Kernel Symbolic Name Syntax, 984

OCF server — ocfserv, 986

ocfserv — OCF server, 986

operating system

- install SunOS/SVR4 — suninstall, 1394
- save core dump — savecore, 1230

operating system, bootable

- load and execute — boot, 131

output system definition

- display current — sysdef, 1420

owner of file

- change — chown, 221

P

pack files and file systems in the cache — cachefspack, 152

packages

- install, upgrade, and remove software — swmtool, 1406

parse clustertoc file based on dynamic entries — parse_dynamic_clustertoc, 987

parse_dynamic_clustertoc — parse clustertoc file based on dynamic entries, 987

passmgmt — password files management, 988

password file

- check for inconsistencies — pwck, 1127

passwords
 installs and updates /etc/shadow with information from /etc/passwd — pwconv, 1128
 management — passmgmt, 988

patchadd — apply a patch package to a Solaris 2 system, 990

patchrm — remove a Solaris patch package and restore previously saved files, 1000

pbind — control and query bindings of processes to processors, 1006
 Binding processes, 1006
 Querying Bindings, 1007
 Unbinding a process, 1007

pcfs
 mount — mount_pcfs, 851

PCMCIA user daemon — pcmciad, 1008

pcmciad — PCMCIA user daemon, 1008

per-processor statistics report — mpstat, 863

perform surface analysis — diskscan, 305

pfinstall — tests installation profiles, 1009

pgxconfig — configure the PGX32 Graphics Accelerator, 1013

PICL daemon — picld, 1018

picld — PICL daemon, 1018

pkgadd — transfer software packages to system, 1024

pkgask — stores answers to an interactive software package, 1027

pkgchk — check package installation accuracy, 1029

pkgrm — remove package from system, 1032

pmconfig — Configure the power management system, 1040

pentadm — DHCP network table management utility, 1042

Point to point protocol daemon — pppd, 1054

populate security attribute databases in a name service — smattrpop, 1280

populate the NIS+ tables in a NIS+ domain — nispopulate, 929

ports
 add or remove a service — pmadm, 1035
 create /dev entries and inittab entries for serial lines — ports, 1049
 enable or disable a service — pmadm, 1035

ports (*continued*)
 install or replace a service configuration script — pmadm, 1035
 print requested service information — pmadm, 1035
 service administration — pmadm, 1035

power manager daemon — powerd, 1053

powerd — power manager daemon, 1053

poweroff — stop the processor, 466

pppd — Point to point protocol daemon, 1054

pppstats — Print PPP statistics, 1087

praudit — display audit trail, 1090

prctmp — accounting shell procedure, 53

prdaily — accounting shell procedure, 53

print device specific information — devinfo, 263

print FRUID-specific information about the FRUs on a system or domain — prtfru, 1109

print PICL tree — prtpicl, 1110

Print PPP statistics, 1087

print queue
 accept or reject requests — accept, reject, 38

print requests
 accept or reject — accept, reject, 38

print service, LP
 — lpmove, 693

printer filters
 add and change — lpfilter, 679
 list attributes — lpfilter, 679
 remove — lpfilter, 679

printer forms
 add or change — lpforms, 684
 delete — lpforms, 686
 list attributes — lpforms, 687
 listing the current alert — lpforms, 689
 provide access — lpforms, 687
 removing an alert definition — lpforms, 689
 setting an alert to mount a form — lpforms, 687
 terminating an active alert — lpforms, 689

printers
 add and change printers — lpadmin, 667
 define alerts for printer faults — lpadmin, 667
 mount printer wheels — lpadmin, 667
 remove printers — lpadmin, 667

printers (*continued*)
 set or change system default destination —
 lpadmin, 667
 setting priorities — lpusers, 700
 printmgr.lm — Solaris Print Manager is a
 graphical user interface for managing
 printers in a network, 1091
 process accounting
 — acctcms, 46
 — accton, 40
 — acctprc, 51
 process scheduler
 administration — dispadmin, 306
 processes
 initialization — init, 516
 kill all active processes — killall, 620
 using file or file structure — fuser, 443
 prodreg — Solaris Product Registry, 1093
 program, standalone
 load and execute — boot, 131
 programming tools
 install — install commands, 554
 projadd —, 1094
 projdel — delete a project from the
 system, 1096
 projmod — modify a project's information on
 the system, 1097
 PROM monitor program — monitor, 819
 PROM monitor program
 display and load program — eeprom, 333
 prstat — report active process statistics, 1099
 prtacct — accounting shell procedure, 53
 prtconf — print system configuration
 information, 1104
 prtdiag — print system diagnostic
 information, 1108
 prtfru — print FRUID-specific information
 about the FRUs on a system or
 domain, 1109
 prtpicl — print PICL tree, 1110
 prtvtoc — print the VTOC of a block
 device, 1111
 psradm — change processor operational
 status, 1113
 psrinfo — displays information about
 processors, 1116

psrset — creation and management of processor
 sets, 1118
 putdev — add, modify remove device entry
 from table, 1122
 putdgrp — add, remove and change device
 group table, 1125

Q

quick halt
 — halt, 466
 quota
 remote quota daemon — rquotad, 1191
 quotas
 check file system quota for inconsistencies —
 quotacheck, 1133
 display a user's disk quota and usage —
 quota, 1132
 displays number of blocks in filesystem
 currently owned by each user —
 quot, 1130
 summarize quotas for a file system —
 repquota, 1142
 turn off file system quotas — quotaoff, 1134
 turn on file system quotas — quotaon, 1134
 quotas, user
 edit — edquota, 331

R

RARP
 server — in.rarpd, 535
 re-preinstall — restore a system to its original
 factory condition, 1143
 real-time clock and GMT-lag management,
 provide — rtc, 1194
 reboot — restart the operating system, 1137
 rebuild NIS database — ypmake, 1547
 register an AnswerBook2 document server with
 FNS (Federated Naming Service) —
 ab2regsvr, 37
 reject — reject print requests, 38
 remote execution server — in.rexecd, 539
 remote login server — in.rlogind, 544

remote system with debugging on, try to contact — Uutry, 1492

remote login server — in.rlogind
rlogind, 544

remote system with debugging on, try to contact — Uutry
uutry, 1492

remote magtape protocol server — rmt, 1148

Remote Program Load Server, *See* rpld

remote resources
mount or unmount — mount, 831
mount NFS — mount_nfs, 842

remote system
execute remote command requests —
uuxqt, 1493
make local resource unavailable for mounting — unshare, 1472
register with LP print service —
lpssystem, 699
set system date — rdate, 1136
shell server — in.rshd, 549
user information server — in.fingerd, 501

removable media mounter for CD-ROM and floppy — rmmount, 1146

remove a Solaris patch package and restore previously saved files — patchrm, 1000

rmovf — remove a file from software database, 1140

removes an application from the Solstice application registry — soldelapp, 1371

report active process statistics — prstat, 1099

report bus-related performance statistics — busstat, 146

report I/O statistics — iostat, 578

restore
incremental file system restore —
ufsrestore, 1465

restore NIS+ directory backup —
nisrestore, 937

return user identity — id, 470

Reverse Address Resolution Protocol, *See* RARP

rlogind — remote login server, 544

rm_drv — remove a device driver from the system, 1139

rmmount — removable media mounter for CD-ROM and floppy, 1146

rmt — remote magtape protocol server, 1148

roleadd — administer a new role account on the system, 1150

roledel — delete a user's login from the system, 1154

rolemod — modify a role's login information on the system, 1156

root directory
change for a command — chroot, 222

route — manually manipulate routing tables, 1159

RPC
kernel statistics server — rpc.rstatd, 1179
network username server —
rpc.rusersd, 1180
network wall server — rpc.rwall, 1181
NIS+ service daemon — rpc.nisd, 1171
program number to universal addresses mapping — rpcbind, 1164
remote execution server — rpc.rexd, 1177
remote quota daemon — rquotad, 1191
report information — rpcinfo, 1167
sends one-way stream of packets to host —
spray, 1375
server which records packets sent by spray —
rpc.sprayd, 1182
server, Autofs mount/unmount requests —
automountd, 126
server, NFS mount requests — mountd, 839

RPC, secure
create a new key in publickey database —
newkey, 889

rpc.bootparamd — boot parameter server, 1166

rpc.nisd — NIS+ service daemon, 1171
rpc.nisd_resolv, 1171, 1174

rpc.nispasswd — NIS+ password update daemon, 1175

rpc.rexd — remote execution daemon, 1177

rpc.rstatd — kernel statistics server, 1179

rpc.ruserd — network username server, 1180

rpc.rwall — network wall server, 1181

rpc.sprayd — records packets sent by spray, 1182

rpc.yppupdated — server for changing NIS information, 1185

rpcbind — converts RPC program numbers to universal addresses, 1164

rpcinfo — report RPC information, 1167
 rpld — IA Network Booting RPL (Remote Program Load) Server, 1186
 rquotad — remote quota server, 1191
 rsh — the restricted shell command interpreter, 1192
 rtc — provide all real-time clock and GMT-lag management, 1194
 run AnswerBook2 server from the Documentation CD — ab2cd, 33
 runacct — run daily accounting, 1195
 rwall — write to all users over a network, 1198
 rwall daemon
 network wall server — rpc.rwalld, 1181

S

s5fs
 mount — mount_s5fs, 853
 sac — Service Access Controller (SAC), 1199
 sacadm — Service Access Controller administration, 1202
 sadmin — Distributed system administration daemon, 1206
 saf — Service Access Facility (SAF), 1211
 SAF
 format and output port monitor-specific information — ttyadm, 1450
 port monitor for terminal ports — ttymon, 1452
 savecore — save OS core dump, 1230
 scheduler, process
 administration — dispadmin, 306
 sckmd — Sun Fire 15000 key management daemon, 1232
 SCSI hardware specific commands for cfgadm — cfgadm_scsi, 195
 select naming service for FNS Initial Context — fnselect, 392
 select or display devices used as auxiliary console devices — consadm, 228
 sendmail — mail delivery system, 1234
 set serial line interface
 set operating parameters — syncinit, 1411
 server for changing NIS information
 — rpc.yupdated, 1185

server for changing NIS information (*continued*)
 — ypupdated, 1185
 servers
 automountd — mount/unmount request server, 126
 biff server — in.comsat, 492
 DARPA TELNET virtual terminal protocol server — in.telnetd, 571
 DARPA trivial name server — in.tnamed, 575
 DHCP server — in.dhcpd, 493
 in.rexecd — remote execution server, 539
 in.uucpd — UUCP server, 576
 inetd — Internet services daemon, 499
 mountd — mount request server, 839
 RARP server — in.rarpd, 535
 system status server — in.rwhod, 552
 talk program server — in.talkd, 570
 yppasswd — NIS password server, 1183
 servers, NIS+
 location information — nis_cachemgr, 916
 Service Access Controller, *See* SAC
 Service Access Facility, *See* SAF
 Service Location Protocol Daemon — sldap, 1270
 set printing configuration — lpset, 696
 set the date and time by way of NTP — ntpdate, 973
 setuname — changes machine information, 1252
 sf880drd — Sun Fire 880 Dynamic Reconfiguration daemon, 1253
 share — make local resource available for mounting by remote systems, 1254
 share_nfs — make local NFS file system available for mounting by remote systems, 1257
 shareall — multiple resources, 1256
 SHELL variable — rsh, 1192
 shell
 remote shell server — in.rshd, 549
 shells
 the restricted shell command interpreter — rsh, 1192
 show Mobile IP Mobility Agent status — mipagentstat, 797
 show network status — netstat, 879

showmount — display remote mounts, 1265
 showrev — displays revision information for current hardware and software, 1266
 shutacct — accounting shell procedure, 53
 shutdown — shutdown system, change system state, 1268
 sldap — Service Location Protocol Daemon, 1270
 smartcard — configure and administer a smartcard, 1272
 smattrpop — populate security attribute databases in a name service, 1280
 smc — start the Solaris Management Console, 1285
 smconf — configure the Solaris Management Console, 1289
 smcron — manage jobs in the crontab database, 1296
 smdiskless — manage diskless client support for a server, 1302
 smexec — manage entries in the exec_attr database, 1308
 smgroup — manage group entries, 1312
 smmaillist — manage email alias entries, 1316
 smmultiuser — manage bulk operations on user accounts, 1320
 smosservice — manage OS services, 1325
 smprofile — manage profiles in the prof_attr and exec_attr databases, 1331
 smrole — manage roles and users in role accounts, 1337
 smuser — manage user entries, 1345
 snmpdx — Sun Solstice Enterprise Master Agent, 1353
 snmpXdmid — Sun Solstice Enterprise SNMP-DMI mapper subagent, 1355
 snoop — capture and inspect network packets, 1357
 soconfig — configure transport providers for use by sockets, 1368
 software package
 add a file to the software installation database — installf, 559
 check installation accuracy — pkgchk, 1029
 remove a file from software database — removef, 1140
 software package (*continued*)
 remove package from system — pkgrm, 1032
 stores answers to an interactive package — pkgask, 1027
 soladdapp — adds an application to the Solstice application registry, 1370
 Solaris Network Cache and Accelerator (NCA) configuration daemon — ncaconfd, 870
 Solaris Print Manager is a graphical user interface for managing printers in a network — printmgr.lm, 1091
 Solaris Product Registry, *See* ProdReg
 Solaris Web Start installer utility — installer, 558
 soldelapp — removes an application from the Solstice application registry, 1371
 solstice — access system administration tools with a graphical user interface, 1372
 SPARCstorage Array
 administration program — ssaadm, 1376
 special NTP query program — xntpdc, 1536
 spray — sends one-way stream of packets to host, 1375
 ssaadm — administration program for the SPARCstorage Array, 1376
 standard Network Time Protocol query program — ntpq, 976
 Start and stop NIS services
 — ypstart, 1556
 Start NIS services
 — ypstart, 1556
 start Sun WBEM User Manager — wbemadmin, 223, 1505
 start the LP print service — lpsched, 695
 start the Solaris Management Console — smc, 1285
 start WBEM Log Viewer — wbemlogviewer, 1509
 startup — accounting shell procedure, 53
 startup procedures — boot, 556
 statd — network status monitor, 1382
 statistics
 audit — auditstat, 115
 for file system — ff, 349
 for ufs file system — ff, 360
 I/O — iostat, 578

statistics (*continued*)
 NFS, display — nfsstat, 895
 per-processor — mpstat, 863
 stop the processor — halt, 466
 stop the processor — poweroff
 poweroff, 466
 Stop NIS services
 — ypstop, 1556
 stop the LP print service — lpshut, 698
 store mail in a mailbox — mail.local, 758
 STREAMS
 automatically pushed modules —
 autopush, 127
 detach a name from file descriptor —
 fdetach, 343
 error logger cleanup program —
 strclean, 1385
 error logger daemon — strerr, 1386
 port monitor for terminal ports —
 ttymon, 1452
 print trace messages — strace, 1383
 su — become super user or another user, 1390
 sulogin — single-user mode automatically
 invoked when system is first started, 1393
 Sun Fire 15000 key management daemon —
 skcmd, 1232
 Sun Fire 880 Dynamic Reconfiguration daemon
 — sf880drd, 1253
 Sun SNMP Agent — mibiisa, 766
 Sun Solstice Enterprise DMI Service Provider —
 dmispd, 315
 Sun Solstice Enterprise Master Agent —
 snmpdx, 1353
 Sun Solstice Enterprise SNMP-DMI mapper
 subagent — snmpXdmid, 1355
 suninstall — install SunOS/SVR4, 1394
 super user command — su, 1390
 swap — administer the system swap
 areas, 1403
 swmtool — install, upgrade and remove
 software packages, 1406
 sxconfig — configure contiguous memory for sx
 video, 1407
 sync — update super block, 1410
 synchronous serial link
 report driver statistics — syncstat, 1417
 synchronous serial loopback test program —
 syncloop, 1414
 syncinit — set serial line interface operating
 parameters., 1411
 syncloop — synchronous serial loopback test
 program, 1414
 syncstat — report driver statistics from a
 synchronous serial link., 1417
 sys-unconfig — undo system
 configuration, 1434
 sysdef — displays current system
 definition, 1420
 syseventd — kernel system event notification
 daemon, 1423
 sysidconfig — execute or define configuration
 applications, 1425
 sysidnet — system configuration, 1428
 sysidpm — system configuration, 1428
 sysidroot — system configuration, 1428
 sysidtool — system configuration, 1428
 syslogd — system log message daemon, 1431
 system activity reports — sar, 1228
 system status server — in.rwhod, 552
 system administration
 access control lists — admintool, 65
 add a file to the software installation
 database — installf, 559
 control for basic administrative functions —
 uadmin, 1457
 create formatted files for manual pages —
 catman, 159
 get entries from administrative database —
 getent, 451
 install commands — install, 554
 NIS+ aliases — aliasadm, 75
 system databases — admintool, 65
 system configuration
 print information — prtconf, 1104
 — sysidnet, 1428
 — sysidpm, 1428
 — sysidroot, 1428
 — sysidtool, 1428
 undo — sys-unconfig, 1434
 system definition
 display current — sysdef, 1420
 system diagnostic
 print information — prtdiag, 1108

- system diagnostic messages
 - error log — dmesg, 308
- system information
 - displays revision information for current hardware and software — showrev, 1266
- system log daemon — syslog, 1431
- system memory
 - examine images — crash, 239
- system parameters
 - change value — setuname, 1252
- System Performance Analysis Utilities Tools
 - system activity report package — sar, 1228
- system PROM monitor program —
 - monitor, 819
- system shutdown
 - halt, 466

T

- tapes — adds /dev entries for tape drives attached to the system, 1436
- TCP/IP
 - File Transfer Protocol daemon on remote host — in.ftpd, 506
- tcxconfig — configure the default linearity of the 24-bit TrueColor Visual for OpenWindows with an S24 frame buffer system (TCX), 1441
- telinit — process control initialization, 516
- terminal
 - compare or print terminfo descriptions — infocmp, 502
 - set type, modes, speed, and line discipline — getty, 454
- terminfo
 - compiler — tic, 1442
- test installation profiles — pfinstall, 1009
- Solaris Network Cache and Accelerator (NCA)
 - door server daemon — ncad, 871
- time zone
 - compiler — zic, 1560
 - print current time in each named on command line — zdump, 1559
- timed event services
 - daemon for cron — cron, 245

- tmpfs
 - mount — mount_tmpfs, 855
- trace a chain of NTP hosts back to their master time source — ntptrace, 983
- trace messages
 - STREAMS — strace, 1383
- transfer software packages to system —
 - pkgadd, 1024
- TTY ports
 - maintain line settings and hunt sequences — sttydefs, 1388
- ttyadm — format and output port monitor-specific information, 1450
- ttymon — port monitor for terminal ports, 1452
- tunefs — tuneup an existing file system, 1455
- turnacct — accounting shell procedure, 53

U

- ufs
 - check and repair — fsck_ufs, 412
 - construct file system — mkfs_ufs, 809
 - display amount of disk space — df_ufs, 281
 - generate a list of pathnames vs i-numbers — ncheck_ufs, 874
 - incremental file system restore — ufsrestore, 1465
 - make image copy of file system — volcopy_ufs, 1500
 - mount — mount_ufs, 858
 - provide labels for ufs — labelit_ufs, 630
- ufs file system debugger — fsdb_ufs, 425
- ufsdump — incremental file system dump, 1458
- umount — unmount file systems and remote resources, 831
- umountall — unmount multiple file systems, 834
- unconfigure
 - undo system configuration — sys-unconfig, 1434
- UNIX system executable file containing basic operating system services — kernel, 615
- unshare — make local resource unavailable for mounting by remote systems, 1472

- unshare_nfs — make local NFS filesystem unavailable for mounting by remote systems, 1473
- unshareall — multiple resources, 1256
- update Internet name servers interactively — nsupdate, 970
- update super block — sync, 1410
- user IDs
 - administer a new user login on the system — useradd, 1474
 - become super user or another user — su, 1390
- user information
 - server, remote — in.fingerd, 501
- user quotas
 - remote quota daemon — rquotad, 1191
- useradd — administer a new user login on the system, 1474
- userdel — delete a user's login from the system, 1479
- usermod — modify a user's login information on the system, 1481
- users
 - list login information — logins, 665
 - who is doing what — whodo, 1511
- utmp and utmpx monitoring daemon — utmpd, 1485
- utmp2wtmp — create an entry for each user logged on in file /var/adm/wtmpx, 40
- utmpd — utmp and utmpx monitoring daemon, 1485
- uuccheck — check the uucp directories and permissions file, 1486
- uucico — file transport program for uucp system, 1487
- uucleanup — uucp spool directory clean-up, 1489
- uucp
 - check directories and permissions file — uuccheck, 1486
 - clean-up of spool directory — uucleanup, 1489
 - file transport program — uucico, 1487
 - scheduler for file transport program — uusched, 1491
 - server — in.uucpd, 576

- uusched — scheduler for uucp transport program, 1491
- Uutry — try to contact remote system with debugging on, 1492
- uutry — try to contact remote system with debugging on, 1492
- uuxqt — execute remote command requests, 1493

V

- virtual console daemon — cvcd, 247
- virtual memory
 - display statistics — vmstat, 1494
- vmstat — display virtual memory statistics, 1494
- vold — Volume Management daemon to manage CD-ROM and floppy devices, 1501
- Volume Management
 - floppy and CD-ROM management daemon — vold, 1501
 - removable media mouter — rmmount, 1146
- vtoc
 - print VTOC of a block device — prtvtoc, 1111

W

- wall — write to all users, 1503
- wbemadmin — start Sun WBEM User Manager, 223, 1505
- wbemconfig — convert a JavaSpaces datastore to the newer Reliable Log datastore format, 1508
- wbemlogviewer — start WBEM Log Viewer, 1509
- whodo — who is doing what, 1511
- wtmpfix — correct connect accounting records date/time stamp, 445

X

- xntpd — Network Time Protocol
 - daemon, 1520
 - Access Control Commands, 1524
 - Authentication Commands, 1523
 - Authentication Key File Format, 1532
 - Configuration Commands, 1521
 - Miscellaneous Commands, 1530
 - Monitoring Commands, 1527
 - Primary Clock Support, 1533
- xntpdcc — special NTP query program, 1536

Y

- YP
 - make ndbm file — makedbm, 760
 - rebuild database — ypmake, 1547
- ypbind — NIS binder process, 1544
- ypinit — set up NIS client, 1546
- ypmake — rebuild NIS database, 1547
- yppoll — return current version of a NIS map at a NIS server host, 1548
- yppush — force propagation of changed NIS map, 1549
- ypserv — NIS server and binder
 - processes, 1551
 - ypserv, 1552
- ypset — point NIS binder process ypbind at a particular server, 1554
- ypstart — Start and stop NIS services, 1556
- ypstop — Start and stop NIS services, 1556
- ypupdated — server for changing NIS information, 1185
- ypxfr — transfer NIS map from a NIS server to host, 1557
- ypxfrd — NIS server and binder
 - processes, 1551
- yppasswd — NIS password server, 1183

Z

- zdump — prints the current time in each zonename named on command line, 1559
- zic — time zone compiler, 1560
